ABSTRACT

The invention relates to rotary units and rotary mechanisms that are suitable for use in numerous applications. Rotary units typically include rotational components that are configured to rotate. In some embodiments, for example, multiple rotary units are assembled in rotary mechanisms such that neighboring pairs of rotational components counter-rotate or contra-rotate relative to one another during operation of the rotary mechanisms. Rotational components generally include one or more implements that are structured to perform or effect one or more types of work as the rotational components rotate relative to one another in a given rotary mechanism. In certain embodiments, implements are configured to rotate and/or to effect the movement of other components as rotational components rotate.

No. 12/577,326, filed Oct. 12, 2009 (now U.S. Pat. No. 8,152,679, issued Apr. 10, 2012), which claims the benefit of priority from U.S. Provisional Patent Application No. 61/104,748, filed on Oct. 12, 2008 and is a continuation of, and claims the benefit of priority from International Patent Application No. PCT/US09/60386, filed on Oct. 12, 2009, which are each incorporated by reference in their entirety. This application is also a continuation-in part of, and claims the benefit of priority from, U.S. Non-Provisional patent application Ser. No. 14/176,119, filed Feb. 9, 2014, which is a continuation of, and claims the benefit of priority from, U.S. Non-Provisional patent application Ser. No. 13/072,656, filed Mar. 25, 2011 (now U.S. Pat. No. 8,662,781, issued Mar. 4, 2014), which claims the benefit of priority from U.S. Provisional Application No. 61/317,746, filed Mar. 26, 2010, which are each incorporated by reference herein in their entirety.

FIELD OF THE INVENTION

The invention relates generally to mechanical, electrical, or electromechanical devices, and provides rotary units, rotary mechanisms, methods, and related devices and other applications that are useful for a wide variety of purposes.

BACKGROUND OF THE INVENTION

Electromechanical devices are ubiquitous. Some of these devices include rotating components and are used in many different applications. Gardening tools such as rotor tillers, for example, typically include rotating rotors having tines, which contact the soil during operation. Many other devices of use in agricultural and construction, among many other fields or applications also utilize various types of rotational components to achieve desired forms of work.

SUMMARY OF THE INVENTION

The invention relates to rotary units and rotary mechanisms that are suitable for use in numerous applications. Rotary units typically include rotational components that are config-

2

ured to rotate. In some embodiments, for example, multiple rotary units are assembled in rotary mechanisms such that neighboring pairs of rotational components counter-rotate or contra-rotate relative to one another during operation of the rotary mechanisms. Rotational components generally include one or more implements that are structured to perform or effect one or more types of work as the rotational components rotate relative to one another in a given rotary mechanism. In certain embodiments, implements are configured to rotate and/or to effect the movement of other components as rotational components rotate. These and many other aspects will be apparent upon a complete review of this disclosure.

In one aspect, the invention provides a rotary unit that includes at least one rotational component comprising at least a first gear component, at least one gear structure receiving area that is configured to receive one or more gear structures or components thereof, and at least a second gear component disposed at least proximal to the gear structure receiving area. The rotary unit also includes at least one gear structure comprising at least one support component and at least one third gear component rotatably coupled to the support component. The third gear component is configured to operably engage the second gear component when the gear structure is at least partially disposed in the gear structure receiving area. In addition, the first gear component is configured to operably engage one or more third gear components of at least one other rotary unit when the rotary unit is disposed proximal to the other rotary unit. In some embodiments of the rotary units of the invention, the rotational component is configured to receive at least one drive mechanism or a portion thereof. In certain embodiments, the other rotary unit operably engages the rotary unit. To further illustrate, in certain embodiments, at least two other rotary units operably engage the rotary unit.

The rotational components of the rotary units and rotary mechanisms of the invention include various embodiments. In some embodiments, for example, the rotational components are coupled to one another via a shaft positioned proximal to an axis of rotation. In certain embodiments, the rotary units and rotary mechanisms of the invention include more than two rotational components (e.g., 3, 4, 5, 6, 7, 8, 9, 10 or more rotational components) in which neighboring pairs of rotational components are configured to substantially simultaneously counter-rotate relative to one another. In some embodiments, a friction reducing material is disposed between the first and second rotational components to reduce friction between the first and second rotational components when the first and second rotational components substantially coaxially rotate relative to one another. In some embodiments, the rotational components substantially coaxially rotate around a rotational axis that is substantially horizontally disposed during operation of the rotary mechanism. Optionally, the rotational components each comprise one or more alignment components structured to align neighboring pairs of rotational components relative to one another. In some of these embodiments, for example, the alignment components comprise a circular ridge disposed on, extending from, or attached to a surface of a first member of a pair of neighboring rotational components and a circular groove disposed in a surface of a second member of the pair of neighboring rotational components, which circular ridge inserts into and rotates in the circular groove in an assembled rotary mechanism. In certain embodiments, the alignment components comprise a circular groove disposed in a surface of each member of the pair of neighboring rotational components and a ring disposed in the grooves of the pair of neighboring rotational components, which grooves rotate about the ring in an assembled rotary mechanism.

Typically, the rotary units or mechanisms of the invention include one or more implements that can be used or adapted for use in many different applications. In certain embodiments, for example, at least one surface of a rotational component comprises at least one implement. Optionally, a rotational component comprises at least one implement that is configured to effect the movement of one or more other components (e.g., a propeller component or the like) when the rotational component rotates and the implement operably engages the other components. In certain embodiments, rotary units or mechanisms include at least one implement rotatably coupled to a rotation component, which implement is configured to operably engage one or more gear components of one or more other rotational components. To illustrate, in some embodiments, the rotary units or mechanisms of the invention include one or more gear components that are configured to operably engage one or more implements rotatably coupled to one or more other rotational components. In some embodiments, a rotary unit or a related rotary mechanism of the invention includes at least one implement rotatably coupled to a rotational component. In these embodiments, the implement is optionally configured to operably engage one or more gear components of at least one other rotary unit when the rotary unit is disposed proximal to the other rotary unit such that the implement rotates when at least the rotational component and the other rotary unit rotate relative to one another. Optionally, at least one implement is disposed in, on and/or extending from at least one surface of a rotational component. In some embodiments, for example, implements include one or more of, e.g., a blade, a razor, a prong, a peg, a claw, a tine, a chain, a stake, a column, a pillar, an arch, a bracket, a gear component, a bristle, a plume, an abrasive component, an elastomeric component, a nail filing component, a nail buffing component, a hair cutting component, a massaging component, a post, etc. To further illustrate, at least a portion of an implement comprises at least one cross-sectional shape selected from, e.g., a circle, an oval, a square, a rectangle, a trapezoid, an irregular n-sided polygon, a regular n-sided polygon, and the like.

In certain embodiments, a device or vehicle includes a rotary unit or mechanism of the invention. In some embodiments, the device is selected from, e.g., a held-held device, a rototiller, a hair cutting device, a massaging device, nail grooming device, a propulsion device, a woodworking device, a lathe, a woodchipping device, a machining device, a dermabrasion device, a medical device, a dental device, a cleaning device, an engine, a snow blower, a nozzle, a food preparation device, a grinder, a pencil sharpener, a lawn mower, a vacuum cleaner, a hair dryer, a plumbing device, a weapon, a surfboard, a scuba device, a component thereof, a combination thereof, etc. In certain embodiments, the vehicle includes a farming vehicle, a mining vehicle, a construction vehicle, a submarine, an aircraft, a marine vehicle, a boat, a personal watercraft, a military vehicle, or the like.

The drive mechanisms used with the rotary units and rotary mechanisms of the invention include various embodiments. In certain embodiments, for example, a drive mechanism comprises at least one motor. Optionally, a drive mechanism comprises one or more of, e.g., a drive shaft, a chain drive, a belt drive, a gear drive, or the like. In some embodiments, a drive mechanism comprises at least one flexible drive shaft. To further illustrate, a drive mechanism is optionally operably coupled to a counter-rotational mechanism and/or rotational components via at least one drive shaft, at least one drive chain, at least one belt drive, and/or at least one gear drive.

In another aspect, the invention provides a rotary mechanism that includes at least first, second, and third rotational

components in which at least one of the rotational components comprises at least one implement. The rotary mechanism also includes at least first and second counter-rotational mechanisms in which the first counter-rotational mechanism operably engages at least the first and second rotational components, and in which the second counter-rotational mechanism operably engages at least the second and third rotational components. In addition, the rotary mechanism also includes at least one drive mechanism component or a portion thereof operably engaged with one or more of the rotational components and/or with one or more of the counter-rotational mechanisms, which drive mechanism component or portion thereof is configured at least to effect rotation of the rotational components and the counter-rotational mechanisms such that the first and third rotational components rotate in a first direction and the second rotational component rotates in a second direction. Typically, the drive mechanism component or portion thereof is configured to effect rotation of the rotational components and the counter-rotational mechanisms such that the first and third rotational components rotate in a second direction and the second rotational component rotates in a first direction. In some embodiments, the rotary mechanisms of the invention include more than three rotational components (e.g., 4, 5, 6, 7, 8, 9, 10 or more rotational components). In certain embodiments, the second rotational component is disposed between the first and third rotational components. Optionally, at least one of the rotational components comprises one or more gear components that are configured to operably engage one or more implements rotatably coupled to one or more other rotational components. In certain embodiments, at least the first counter-rotational mechanism comprises at least a first gear component disposed on the first rotational component, at least a second gear component disposed on the second rotational component, and at least a third gear component that operably engages the first and second gear components such that when the first gear component rotates in the first direction, the second and third gear components rotate in the second direction and when the first gear component rotates in the second direction, the second and third gear components rotate in the first direction. In some of these embodiments, the rotary mechanism includes a retaining mechanism that retains the third gear component operably engaged with the first and second gear components. In some of these embodiments, the second gear component substantially defines a gear receiving area that is configured to receive at least a portion of the third gear component. Gear components used with the rotary units, rotary mechanisms, and other applications of the invention typically include gear teeth. Any operable gear tooth configuration and/or type are optionally used in the rotary units, rotary mechanisms and applications of the invention.

In one aspect, the invention provides a rotary unit that includes at least a first rotational component configured to rotate around a rotational axis, which first rotational component comprises at least first and second surfaces. The first surface comprises one or more gear components that are configured to operably engage one or more gear components of at least a second rotational component (e.g., of a second rotary unit, etc.) when the first rotational component is disposed proximal to the second rotational component such that when the first rotational component rotates in a first direction, the second rotational component rotates in a second direction. The second surface comprises one or more gear components that are configured to operably engage one or more gear components of at least a third rotational component (e.g., of a third rotary unit, etc.) when the first rotational component is disposed proximal to the third rotational component such that

5

when the first rotational component rotates in the first direction, the third rotational component rotates in the second direction. In addition, at least one surface of the first rotational component comprises at least one implement, which surface is configured to rotate substantially non-perpendicular to the rotational axis. In some embodiments, the surface of the first rotational component that comprises the implement is configured to rotate substantially parallel to the rotational axis. In some embodiments, the first surface comprises one or more sun gear components. In certain embodiments, the second surface comprises one or more ring gear components. In some embodiments, a rotational mechanism comprises the rotary unit. In some embodiments, at least one of the surfaces of the first rotational component comprises at least one friction reducing material. In certain of these embodiments, for example, the friction reducing material is selected from, e.g., a coating, a lubricant, a surface feature, a roller ball, and the like.

In another aspect, the invention provides a rotary mechanism that includes at least two rotary units that each comprises at least one rotational component that comprises at least a first gear component, and at least one second gear component configured to operably engage the first gear component. The rotary mechanism also includes at least one drive mechanism component or portion thereof that operably engages at least the second gear components of at least first and second rotary units. The drive mechanism component or portion thereof is configured to effect rotation of the second gear components such that the rotational component of the first rotary unit rotates in a first direction and the rotational component of the second rotary unit rotates in a second direction. In some embodiments, the first gear component comprises at least one ring gear component. In certain embodiments, at least one surface of at least one of the rotational components comprises at least one implement. In these embodiments, the surface is optionally configured to rotate substantially non-perpendicular to a rotational axis of the rotational components. In other of these embodiments, the surface is optionally configured to rotate substantially parallel to a rotational axis of the rotational components. In some embodiments, the rotary mechanism includes at least one positioning component that is configured to position the rotary units relative to one another. In some of these embodiments, the positioning component comprises a frame structure. Optionally, at least one surface of the positioning component comprises at least one friction reducing material.

In another aspect, the invention provides a rotary mechanism that includes at least two rotary units that each comprise at least one rotational component that comprises at least one sun gear component and at least one ring gear component, and at least one gear structure that comprises at least one support component and at least one planetary gear component rotatably coupled to the support component. The planetary gear component is configured to operably engage the ring gear component. In addition, the sun gear component of at least a first rotary unit operably engages the planetary gear component of at least a second rotary unit such that when the rotational component of the first rotary unit rotates in a first direction, the rotational component of the second rotary unit rotates in a second direction. In some embodiments, the gear structure of the first rotary unit is operably connected to the gear structure of the second rotary unit such that the support components are substantially fixedly positioned relative to one another at least when the rotational component of the first rotary unit rotates in the first direction, the rotational component of the second rotary unit rotates in the second direction. Typically, at least one of the rotational components comprises

6

at least one implement. In some embodiments, at least two of the rotational components are non-concentrically disposed relative to one another. In some embodiments, the rotary mechanism includes at least three, at least four, at least five, at least six, at least seven, at least eight, at least nine, at least ten, or more rotary units.

In another aspect, the invention provides a rotary unit that includes at least one rotational component comprising at least first and second gear components and at least one gear structure receiving area. The first gear component substantially fixedly extends from a first surface of the rotational component. The first gear component is configured to operably engage one or more other gear components of another rotary unit when the first gear component is disposed proximal to the other gear components. The second gear component substantially fixedly extends from a second surface of the rotational component. The second gear component communicates with the gear structure receiving area. The gear structure receiving area is configured to receive one or more gear structures or components thereof. In addition, at least one surface of the rotational component comprises at least one implement. The rotary unit includes at least one gear structure comprising at least one support component and at least a third gear component rotatably coupled to the support component. The third gear component is configured to operably engage one or more other gear components when the third gear component is disposed proximal to the other gear components. Further, the rotational component is configured to rotate relative to the support component, which support component is substantially fixedly positioned when the rotational component rotates relative to the support component. Typically, the first and second surfaces substantially oppose one another. The third gear component is typically configured to rotate relative to the rotational component. In some embodiments, the first gear component comprises at least one sun gear component. In certain embodiments, the second gear component comprises at least one ring gear component. In some embodiments, the third gear component comprises at least one planetary gear component. In certain embodiments, the surface of the rotational component that comprises the implement is configured to rotate substantially non-perpendicular to a rotational axis of the rotary unit. In some embodiments, the surface of the rotational component that comprises the implement is configured to rotate substantially parallel to a rotational axis of the rotary unit. Typically, a rotational mechanism comprises the rotary unit.

In another aspect, the invention provides a rotary unit that includes at least a first rotational component that comprises at least first and second surfaces. The first surface comprises at least a first gear component and the second surface comprises at least a second gear component, which first and second gear components are substantially fixed relative to one another. The first gear component is configured to operably engage one or more third gear components that are configured to operably engage one or more second gear components of at least a second rotational component when the first rotational component is disposed proximal to the second rotational component such that when the first rotational component rotates in a first direction, the second rotational component rotates in a second direction. The second gear component is configured to operably engage one or more third gear components that are configured to operably engage one or more first gear components of at least a third rotational component when the first rotational component is disposed proximal to the third rotational component such that when the first rotational component rotates in the first direction, the third rotational component rotates in the second direction. In addition,

the third gear components are configured to rotate in substantially fixed positions relative to one another. In some embodiments, the first gear component comprises at least one sun gear component. In certain embodiments, the second gear component comprises at least one ring gear component. In some embodiments, the third gear components comprise at least one planetary gear component. Typically, one or more gear structures comprise the third gear components. In some embodiments, a rotational mechanism comprises the rotary unit. Typically, at least one surface of the first rotational component comprises at least one implement. In some of these embodiments, the surface of the first rotational component that comprises the implement is configured to rotate substantially non-perpendicular to a rotational axis of the rotary unit. In some of these embodiments, the surface of the first rotational component that comprises the implement is configured to rotate substantially parallel to a rotational axis of the rotary unit.

In another aspect, the invention provides a rotary mechanism that includes at least first, second, and third rotational components in which at least one of the rotational components comprises at least one implement. The rotary mechanism also includes at least first and second counter-rotational mechanisms in which the first counter-rotational mechanism operably engages at least the first and second rotational components. The second counter-rotational mechanism operably engages at least the second and third rotational components. Further, at least portions of the first and second counter-rotational mechanisms are substantially fixedly positioned relative to one another. In addition, the rotary mechanism also includes at least one drive mechanism component or a portion thereof operably engaged with one or more of the rotational components and/or with one or more of the counter-rotational mechanisms. The drive mechanism component or portion thereof is configured at least to effect rotation of the rotational components and the counter-rotational mechanisms such that the first and third rotational components rotate in a first direction and the second rotational component rotates in a second direction.

In another aspect, the invention provides a rotary unit that includes at least a first rotational component that comprises at least one sun gear component and at least one ring gear component. The sun gear component is configured to operably engage one or more gear components of at least a second rotational component such that when the first rotational component rotates in a first direction the second rotational component rotates in a second direction. The ring gear component at least partially defines at least one gear structure receiving area. The rotary unit also includes at least one gear structure at least partially disposed in the gear structure receiving area. The gear structure comprises at least one support component and at least one planetary gear component rotatably coupled to the support component. The support component is substantially fixedly positioned when the planetary gear component rotates relative to the support component. The planetary gear component is configured to operably engage the ring gear component and one or more gear components of at least a third rotational component such that when the first rotational component rotates in the first direction the third rotational component rotates in the second direction. In some embodiments, the support component is configured to operably engage one or more other support components of one or more other rotational components such that the support components are substantially fixedly positioned relative to one another when the rotational components rotate. Typically, the

first rotational component comprises at least one implement. In some embodiments, a rotary mechanism comprises the rotary unit.

In another aspect, the invention provides a rotary mechanism that includes at least one drive mechanism component or a portion thereof comprising at least one ring gear component and at least one gear structure that comprises at least one support component and at least one planetary gear component rotatably coupled to the support component, which planetary gear component is configured to operably engage the ring gear component. In addition, the rotary mechanism also includes at least one rotary unit that comprises at least one rotational component comprising at least one ring gear component and at least one sun gear component, and at least one gear structure that comprises at least one support component and at least one planetary gear component rotatably coupled to the support component, which planetary gear component is configured to operably engage the ring gear component. The planetary gear component of the drive mechanism component or a portion thereof is configured to operably engage the sun gear component of the rotary unit such that when the drive mechanism component or a portion thereof effects rotation of the ring gear component of the drive mechanism component or a portion thereof in a first direction, the rotational component of the rotary unit rotates in a second direction. In some embodiments, at least one of the rotational components and/or the ring gear component of the drive mechanism component or the portion thereof comprises at least one implement. In some embodiments, the gear structure of the drive mechanism component or the portion thereof is operably connected to the gear structure of the rotary unit such that the support components are substantially fixedly positioned relative to one another at least when the ring gear component of the drive mechanism component or the portion thereof rotates in the first direction, the rotational component of the rotary unit rotates in the second direction. In certain embodiments, the rotary mechanism includes at least three, at least four, at least five, at least six, at least seven, at least eight, at least nine, at least ten, or more rotary units.

In another aspect, the invention provides a rotary or rotational mechanism that includes at least a first rotary unit that comprises at least one rotational component that comprises at least first and second sun gear components. The rotational mechanism also includes at least a second rotary unit that comprises at least one rotational component that comprises at least first and second ring gear components. In addition, the rotational mechanism also includes at least a first planetary gear component that is configured to operably engage the second sun gear component of the first rotary unit and the first ring gear component of the second rotary unit such that when the rotational component of the first rotary unit rotates in a first direction, the rotational component of the second rotary unit rotates in a second direction.

In some embodiments, the rotational components of the first and second rotary units are configured to rotate at different rates relative to one another. In some embodiments, the rotational mechanism includes at least one gear structure that comprises at least one support component in which the first planetary gear component is rotatably coupled to the support component. In certain embodiments, the rotational mechanism includes at least a second planetary gear component that is configured to operably engage one or more gear components of at least a third rotary unit and the second ring gear component of the second rotary unit such that when the rotational component of the second rotary unit rotates in the second direction, a rotational component of the third rotary unit rotates in the first direction.

In some embodiments, the first sun gear component of the first rotary unit is configured to operably engage one or more gear components of at least a fourth rotary unit such that when the rotational component of the first rotary unit rotates in the first direction, a rotational component of the fourth rotary unit rotates in the second direction. In some of these embodiments, the first sun gear component of the first rotary unit is configured to operably engage the one or more gear components of the fourth rotary unit via one or more planetary gear components.

In certain embodiments, the rotational mechanism includes more than two rotary units. In some of these embodiments, a sum of rotational rates of the rotational components of a first pair of neighboring rotary units is configured to be substantially identical to a sum of rotational rates of the rotational components of a second pair of neighboring rotary units when the rotational components rotate relative to one another.

In another aspect, the invention provides a cleaning device that includes at least one head component that comprises at least one cleaning material support component and at least one cleaning surface component. In some embodiments, the cleaning surface component comprises at least one elevational element. The cleaning material support component comprises at least one cleaning material support surface that at least partially defines at least one cleaning material cartridge receiving area. The cleaning material support component comprises at least one opening such that the cleaning material cartridge receiving area communicates with the cleaning surface component. In addition, the cleaning material cartridge receiving area is configured to receive at least one cleaning material cartridge comprising cleaning material such that at least a portion of the cleaning material is movable to and/or from the cleaning material cartridge receiving area to extend over at least a portion of the cleaning surface component when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. The cleaning device also includes at least one rotary mechanism comprising at least one rotational component that comprises at least one implement.

In some embodiments, the rotary mechanism of the cleaning device comprises at least first, second, and third rotational components. In these embodiments, the rotary mechanism also includes at least first and second counter-rotational mechanisms. The first counter-rotational mechanism operably engages at least the first and second rotational components. The second counter-rotational mechanism operably engages at least the second and third rotational components. In these embodiments, the rotary mechanism also includes at least one drive mechanism component or a portion thereof operably engaged with one or more of the rotational components and/or with one or more of the counter-rotational mechanisms, which drive mechanism component or portion thereof is configured at least to effect rotation of the rotational components and the counter-rotational mechanisms such that the first and third rotational components rotate in a first direction and the second rotational component rotates in a second direction. In some of these embodiments, the implement comprises a plurality of bristles.

In some embodiments, the cleaning device includes at least one positioning mechanism component that is configured to selectively position the cleaning material at least relative to the cleaning material support component when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. In some embodiments, the cleaning device includes at least two cleaning material support components that are each configured to receive at least a

component of the cleaning material cartridge. In some embodiments, the cleaning device includes at least one retaining component that is configured to substantially retain the cleaning material cartridge at a selected position relative to the cleaning material support component when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. In some embodiments, the cleaning device includes at least one retaining mechanism that is configured to substantially retain the cleaning material at a selected position relative to the cleaning surface component when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area and the cleaning material extends over at least the portion of the cleaning surface component. In some embodiments, the cleaning device includes the cleaning material cartridge at least partially disposed in the cleaning material cartridge receiving area of the cleaning material support component. In some embodiments, the cleaning device includes at least one handle operably connected to the head component. In some of these embodiments, the handle is pivotally connected to the head component via at least one pivot mechanism.

In some embodiments, the cleaning device includes at least one conveyance mechanism, or at least one component thereof, that is configured to convey at least the cleaning material over at least the portion of the cleaning surface component when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. In some embodiments, the conveyance mechanism is manually operated via at least one manual conveyance component. In some embodiments, the conveyance mechanism or the component thereof is configured to operably engage the cleaning material cartridge to effect conveyance of the cleaning material when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. In some embodiments, the conveyance mechanism is configured to convey the cleaning material at least one selected incremental distance. In some embodiments, the conveyance mechanism comprises one or more gear components. In some embodiments, the conveyance mechanism comprises at least one motor component that is configured to effect conveyance of the cleaning material when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area.

In some embodiments, the cleaning device includes at least one fluid handling mechanism or at least one component thereof that is configured to convey at least one fluid from at least one fluid source to at least one fluid outlet. In some embodiments, the fluid outlet communicates with the cleaning material cartridge or a portion thereof when the cleaning material cartridge is at least partially disposed in the cleaning material cartridge receiving area. In some embodiments, the fluid outlet is disposed proximal to at least one surface of the head component. In some embodiments, the fluid outlet comprises at least one nozzle. In some embodiments, the fluid handling mechanism comprises at least one pumping mechanism that is configured to pump the fluid from the fluid source to the fluid outlet. In some embodiments, the fluid handling mechanism comprises at least one vaporization component that is configured to vaporize the fluid at least proximal to the fluid outlet. In some embodiments, the fluid source and fluid outlet communicate via at least one fluid conduit. In some embodiments, the fluid source comprises at least one fluid container. In some of these embodiments, the fluid container is removable.

In another aspect, the invention provides a device that includes at least two rotational units, and at least one rotary mechanism configured to operably engage at least one of the

11

rotational units to effect counter-rotation of neighboring pairs of the rotational units. In some embodiments, at least one of the rotational units comprises at least one propeller unit.

In another aspect, the invention provides a device that includes at least two rotational units in which at least one of the rotational units comprises at least one implement and at least one gear component, and at least one rotary mechanism that operably engages the gear component such that when the rotary mechanism rotates, neighboring pairs of rotational units counter-rotate relative to one another. In some embodiments, the device includes at least three, at least four, at least five, at least six, at least seven, at least eight, at least nine, at least ten, or more rotational units. In certain embodiments, the implement comprises at least one propeller component. In some embodiments, at least one surface of the at least one rotational unit comprises the gear component, which surface is configured to rotate substantially non-perpendicular to a rotational axis of the rotational units and/or the rotary mechanism. In certain embodiments, the gear component is disposed at least partially around the implement. In some embodiments, the rotary mechanism comprises at least two rotary units that operably engage gear components of different rotational units in which the rotary units are configured to counter-rotate relative to one another. In some embodiments, at least one of the rotational units and/or the rotary mechanism comprises at least one rotational alignment component. In certain embodiments, the device includes at least one drive mechanism operably connected to the rotational units and/or to the rotary mechanism. In some embodiments, the device includes at least one positioning component (e.g., a housing, a frame structure, or the like) configured to position the rotational units and the rotary mechanism relative to one another. In some embodiments, the device includes at least two rotary mechanisms, wherein at least a first rotary mechanism operably engages the gear component of at least a first rotational unit, wherein at least a second rotary mechanism operably engages the gear component of at least a second rotational unit, and wherein the first rotary mechanism is configured to rotate in at least a first direction and the second rotary mechanism is configured to rotate in at least a second direction such that when the first and second rotary mechanisms rotate, the first rotational unit rotates in the first direction and the second rotational unit rotates in the second direction. In some of these embodiments, the first rotary mechanism operably engages the gear components of at least a first set of non-neighboring rotational units and wherein the second rotary mechanism operably engages the gear components of at least a second set of non-neighboring rotational units.

In another aspect, the invention provides a cleaning device that includes at least one rotary mechanism that comprises at least two rotational components that are non-concentrically disposed relative to one another and are configured to counter-rotate relative to one another around a rotational axis in which at least one surface of at least one of the rotational components comprises at least one implement (e.g., bristles or the like), which surface is configured to rotate substantially non-perpendicular to the rotational axis. In some embodiments, the rotary mechanism comprises at least three, at least four, at least five, at least six, at least seven, at least eight, at least nine, at least ten, or more rotational components. In some embodiments, the cleaning device includes at least one head component in which the rotary mechanism is at least partially disposed within the head component. Optionally, at least one handle is operably connected to the head component.

In some embodiments, the cleaning device includes at least one fluid handling mechanism or at least one component

12

thereof that is configured to convey at least one fluid from at least one fluid source to at least one fluid outlet. In certain embodiments, the fluid outlet is disposed proximal to at least one surface of a head component. In some embodiments, the fluid outlet comprises at least one nozzle. In certain embodiments, the fluid handling mechanism comprises at least one pumping mechanism that is configured to pump the fluid from the fluid source to the fluid outlet. In some embodiments, the fluid handling mechanism comprises at least one vaporization component that is configured to vaporize the fluid at least proximal to the fluid outlet. In some embodiments, the fluid source and fluid outlet communicate via at least one fluid conduit. In certain embodiments, the fluid source comprises at least one fluid container. In some embodiments, the fluid container is removable.

In certain embodiments, the cleaning device includes at least one suction component that comprises at least one inlet and at least one outlet. Typically, the suction component comprises at least one vacuum source. In some embodiments, the inlet is disposed proximal to the rotary mechanism and/or a head component that at least partially comprises the rotary mechanism. In some embodiments, the cleaning device includes at least one waste container in which the outlet of the suction component communicates with the waste container. In some embodiments, the outlet and the waste container communicate via at least one conduit. In certain embodiments, the waste container is removable.

In another aspect, the invention provides methods of rotating implements. In some embodiments, the methods include providing a rotary mechanism comprising at least two rotary units that each comprises at least one rotational component that comprises at least a first gear component, and at least one second gear component configured to operably engage the first gear component; and, at least one drive mechanism component or portion thereof that operably engages at least the second gear components of at least first and second rotary units, wherein at least one surface of at least one of the rotational components comprises at least one implement; and, moving at least the portion of the drive mechanism such that the rotational component of the first rotary unit rotates in a first direction and the rotational component of the second rotary unit rotates in a second direction, thereby rotating the implement.

In one aspect, the invention provides a rotary mechanism that includes at least two rotational components that each comprises at least one ring gear component. The rotary mechanism also includes at least one counter-rotational mechanism that comprises at least a first gear component that operably engages the ring gear component of at least a first rotational component, at least a second gear component that operably engages the ring gear component of at least a second rotational component, and at least a third gear component that operably engages at least the second gear component such that when the first gear component rotates in a first direction, the first rotational component rotates in the first direction and the second gear component and the second rotational component rotate in a second direction.

In some embodiments, the rotary mechanism includes one or more alignment components that align at least the first and second rotational components relative to one another when the rotational components rotate. In certain embodiments, the first rotational component comprises at least one alignment component and the second rotational component comprises at least one alignment component receiving area that is configured to receive at least a portion of the alignment component of the first rotational component to align the first and second rotational components relative to one another when the rota-

13

tional components rotate. In some embodiments, at least two of the rotational components each comprises at least one alignment component and at least one alignment component receiving area, wherein the alignment component receiving area of at least one of the rotational components is configured to receive at least a portion of the alignment component of at least one other rotational component to align the rotational components relative to one another when the rotational components rotate. In certain embodiments, the rotary mechanism includes three or more rotational components. In some embodiments, a device or vehicle includes the rotary mechanism.

In some embodiments, the rotary mechanism includes at least one drive mechanism component or portion thereof that operably engages at least the first gear component, which drive mechanism component or portion thereof is configured to effect rotation of at least the first gear component. In certain embodiments, the drive mechanism component or portion thereof operably engages the third gear component. In certain embodiments, the drive mechanism component or portion thereof comprises at least one shaft component that operably engages at least the first gear component.

In certain embodiments, at least one surface of at least one of the rotational components comprises at least one implement. In some embodiments, the surface is configured to rotate substantially non-perpendicular to a rotational axis of the rotational components. In some embodiments, the surface is configured to rotate substantially parallel to a rotational axis of the rotational components. In certain embodiments, the implement is rotatably coupled to the rotational component. In some of these embodiments, the implement is configured to operably engage one or more gear components of one or more other rotational components.

In another aspect, the invention provides a rotary mechanism that includes at least two rotational components that each comprises at least a first gear component. The rotary mechanism also includes at least one counter-rotational mechanism that comprises at least a second gear component that operably engages the first gear component of at least a first rotational component, at least a third gear component that operably engages the first gear component of at least a second rotational component, and at least a fourth gear component that operably engages at least the third gear component such that when the second gear component rotates in a first direction, the first rotational component rotates in the first direction and the third gear component and the second rotational component rotate in a second direction. In some embodiments, the first gear component comprises at least one ring gear component.

In another aspect, the invention provides a rotary unit that includes at least a first rotational component configured to rotate around a rotational axis, which first rotational component comprises at least one ring gear component and at least one surface that comprises at least one implement. The rotary unit also includes at least first gear component that operably engages the ring gear component such that when the first gear component rotates in a first direction, the first rotational component rotates in the first direction.

In some embodiments, the rotary unit includes at least a third gear component configured to operably engage at least a second gear component of at least a second rotational component when the second rotational component is disposed proximal to the first rotational component such that when the first gear component rotates in the first direction, the first rotational component rotates in the first direction and the second gear component and the second rotational component rotate in a second direction. In certain embodiments, the first

14

rotational component comprises at least one alignment component and/or at least one alignment component receiving area that is configured to align at least the first rotational component relative to at least one other rotational component when the other rotational component is disposed proximal to the first rotational component. In some embodiments, the surface that comprises the implement is configured to rotate substantially non-perpendicular to the rotational axis of the first rotational component. In some embodiments, the surface that comprises the implement is configured to rotate substantially parallel to the rotational axis of the first rotational component.

In some embodiments, the rotary unit includes at least one drive mechanism component or portion thereof that operably engages at least the first gear component, which drive mechanism component or portion thereof is configured to effect rotation of at least the first gear component. In certain embodiments, the drive mechanism component or portion thereof operably engages at least one other gear component. In some embodiments, the drive mechanism component or portion thereof comprises at least one shaft component that operably engages at least the first gear component. In certain embodiments, the drive mechanism component or portion thereof comprises at least one drive mechanism component receiving area that is configured to receive and operably engage at least a portion of at least one other drive mechanism component of at least one other rotary unit.

In another aspect, the invention provides a method of rotating an implement. The method includes providing at least one rotary mechanism that comprises at least two rotational components that each comprises at least one ring gear component. The rotary mechanism also includes at least one counter-rotational mechanism that comprises at least a first gear component that operably engages the ring gear component of at least a first rotational component, at least a second gear component that operably engages the ring gear component of at least a second rotational component, and at least a third gear component that operably engages the second gear component, wherein the first and/or second rotational component comprises at least one implement. The method also includes rotating the first gear component in a first direction such that the third gear component and the first rotational component rotate in the first direction and the second gear component and the second rotational component rotate in a second direction, thereby rotating the implement.

In another aspect, the invention provides a method of making a rotary unit. The method includes forming at least a first rotational component that comprises at least one ring gear component and forming at least first gear component. The method also includes positioning the first gear component in operable engagement with the ring gear component of the first rotational component such that when the first gear component rotates in a first direction, the first rotational component rotates in the first direction, thereby making the rotary unit. In some embodiments, the method includes forming the first rotational component to comprise at least one implement.

In certain embodiments, the method includes forming the first gear component to comprise at least one shaft component. In some embodiments, the method also includes forming at least second and third gear components, forming at least a second rotational component that comprises at least one ring gear component, and positioning the second gear component in operable engagement with the ring gear component of the second rotational component and the third gear component in operable engagement with the second gear component such that when the first gear component rotates in the first direction, the third gear component and the first

15

rotational component rotate in the first direction and the second gear component and the second rotational component rotate in a second direction. In certain embodiments, the method includes forming the second rotational component to comprise at least one implement. In some embodiments, the method includes forming the first and third gear components to comprise at least one shaft component. In some embodiments, the method includes forming the second gear component to comprise at least one shaft component.

In another aspect, the invention provides a rotary mechanism that includes at least two rotary units that each comprises at least one rotational component that comprises at least one ring gear component, and at least one second gear component configured to operably engage the ring gear component. The rotary mechanism also includes at least one drive mechanism component or portion thereof that operably engages at least the second gear components of at least first and second rotary units. The drive mechanism component or portion thereof is configured to effect rotation of the second gear components such that the rotational component of the first rotary unit rotates in a first direction and the rotational component of the second rotary unit rotates in a second direction.

In some embodiments, the rotary mechanism includes three or more rotary units. In certain embodiments, the rotary mechanism includes at least one drive mechanism positioning component configured to position at least drive mechanism components or portions thereof relative to one another. In some embodiments, the drive mechanism component or portion thereof comprises at least two shaft components, wherein at least a first shaft component operably engages at least the second gear component of the first rotary unit and at least a second shaft component operably engages at least the second gear component of the second rotary unit. In some of these embodiments, the first and second shaft components each comprise at least one drive gear component that operably engage (e.g., mesh with) one another. In certain embodiments, a device or vehicle includes the rotary mechanism operably connected thereto.

In some embodiments, at least one of the rotational components comprises at least one implement. In certain embodiments, at least one surface of at least one of the rotational components comprises at least one implement. In some of these embodiments, the surface is configured to rotate substantially non-perpendicular to a rotational axis of the rotational components. In certain embodiments, the surface is configured to rotate substantially parallel to a rotational axis of the rotational components. In certain embodiments, the implement is rotatably coupled to the rotational component. In some of these embodiments, the implement is configured to operably engage one or more gear components of one or more other rotational components.

In certain embodiments, the rotary mechanism includes one or more alignment components that align at least the rotational components relative to one another when the rotational components rotate. In some embodiments, the rotational component of the first rotary unit comprises at least one alignment component and the rotational component of the second rotary unit comprises at least one alignment component receiving area that is configured to receive at least a portion of the alignment component of the rotational component of the first rotary unit to align the rotational components of the first and second rotary units relative to one another when the rotational components rotate. In some embodiments, at least two of the rotational components each comprises at least one alignment component and at least one alignment component receiving area, wherein the alignment

16

component receiving area of at least one of the rotational components is configured to receive at least a portion of the alignment component of at least one other rotational component to align the rotational components relative to one another when the rotational components rotate.

BRIEF DESCRIPTION OF THE DRAWINGS

The description provided herein is better understood when read in conjunction with the accompanying drawings which are included by way of example and not by way of limitation. It will be understood that like reference numerals identify like components throughout the drawings, unless the context indicates otherwise. It will also be understood that some or all of the figures may be schematic representations for purposes of illustration and do not necessarily depict the actual relative sizes or locations of the elements shown. In addition, in certain figures implements are schematically illustrated as cross-hatches on rotary units.

FIG. 1A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 1B schematically shows the rotary unit of FIG. 1A from a rear side view. FIG. 1C schematically depicts the rotary unit of FIG. 1A from a side view. FIG. 1D schematically shows a gear structure of the rotary unit of FIG. 1A from a rear side view. FIG. 1E schematically illustrates the gear structure of FIG. 1D from a front side view. FIG. 1F schematically shows the gear structure of FIG. 1D from a side view. FIG. 1G schematically illustrates a sectional view of the rotary unit of FIG. 1A. FIG. 1H schematically shows a sectional view of the rotary unit of FIG. 1A. FIG. 1I schematically depicts a partially exploded view of the rotary unit of FIG. 1A.

FIGS. 2 A-F schematically show side elevational views of various exemplary implements.

FIG. 3A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 3B schematically shows the rotary unit of FIG. 3A from a rear side view. FIG. 3C schematically shows the rotary unit of FIG. 3A from a side view. FIG. 3D schematically depicts a sectional view of the rotary unit of FIG. 3A. FIG. 3E schematically shows a gear structure of the rotary unit of FIG. 3A from a rear side view. FIG. 3F schematically shows a gear structure of the rotary unit of FIG. 3A from a front side view. FIG. 3G schematically shows a gear structure of the rotary unit of FIG. 3A from a side view.

FIG. 4A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 4B schematically shows the rotary unit of FIG. 4A from a rear side view. FIG. 4C schematically shows the rotary unit of FIG. 4A from a side view. FIG. 4D schematically depicts a sectional view of the rotary unit of FIG. 4A. FIG. 4E schematically shows a gear structure of the rotary unit of FIG. 4A from a front side view. FIG. 4F schematically shows a gear structure of the rotary unit of FIG. 4A from a rear side view. FIG. 4G schematically shows a gear structure of the rotary unit of FIG. 4A from a side view.

FIG. 5A schematically illustrates a rotary unit from a side view according to one embodiment of the invention. FIG. 5B schematically shows a sectional view of the rotary unit of FIG. 5A.

FIG. 6A schematically shows a rotary unit from a front side view according to one embodiment of the invention. FIG. 6B schematically illustrates the rotary unit of FIG. 6A from a side view. FIG. 6C schematically depicts the rotary unit of FIG. 6A from a rear side view. FIG. 6D schematically shows a sectional view of the rotary unit of FIG. 6A. FIG. 6E schematically illustrates a gear structure of the rotary unit of FIG. 6A.

17

6A from a rear side view. FIG. 6F schematically shows the gear structure of FIG. 6E from a front side view. FIG. 6G schematically illustrates the gear structure of FIG. 6E from a front side view.

FIG. 7A schematically shows a rotary unit from a front side view according to one embodiment of the invention. FIG. 7B schematically shows the rotary unit of FIG. 7A from a rear side view. FIG. 7C schematically depicts the rotary unit of FIG. 7A from a side view.

FIG. 8A schematically shows a rotary unit from a front side view according to one embodiment of the invention. FIG. 8B schematically shows the rotary unit of FIG. 8A from a rear side view. FIG. 8C schematically depicts the rotary unit of FIG. 8A from a side view.

FIG. 9A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 9B schematically shows the rotary unit of FIG. 9A from a rear side view. FIG. 9C schematically depicts the rotary unit of FIG. 9A from a side view. FIG. 9D schematically shows schematically shows a sectional view of the rotary unit of FIG. 9A. FIG. 9E schematically illustrates a sectional view of the rotary unit of FIG. 9A. FIG. 9F schematically shows a gear structure of the rotary unit of FIG. 9A from a rear side view. FIG. 9G schematically illustrates the gear structure of FIG. 9F from a front side view. FIG. 9H schematically shows the gear structure of FIG. 9F from a side view. FIG. 9I schematically depicts a partially exploded view of the rotary unit of FIG. 9A. FIG. 9J schematically shows the rotary unit of FIG. 9A with implements from a rear side view. FIG. 9K schematically shows the rotary unit of FIG. 9A with implements from a front side view. FIG. 9L schematically shows the rotary unit of FIG. 9A with implements from a side view.

FIG. 10A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 10B schematically shows the rotary unit of FIG. 10A from a rear side view. FIG. 10C schematically depicts the rotary unit of FIG. 10A from a side view. FIG. 10D schematically shows schematically shows a sectional view of the rotary unit of FIG. 10A. FIG. 10E schematically shows a gear structure of the rotary unit of FIG. 10A from a front side view. FIG. 10F schematically illustrates the gear structure of FIG. 10E from a rear side view. FIG. 10G schematically shows the gear structure of FIG. 10E from a side view. FIG. 10H schematically illustrates a sectional view of the rotary unit of FIG. 10A. FIG. 10I schematically depicts the rotary unit of FIG. 10A including a friction reducing material from a front side view. FIG. 10J schematically depicts the rotary unit of FIG. 10A including a friction reducing material from a side view. FIG. 10K schematically shows the rotary unit of FIG. 10I with implements from a front side view. FIG. 10L schematically shows the rotary unit of FIG. 10A with implements from a rear side view. FIG. 10M schematically shows the rotary unit of FIG. 10I with implements from a side view.

FIG. 11A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 11B schematically shows the rotary unit of FIG. 11A from a rear side view. FIG. 11C schematically depicts the rotary unit of FIG. 11A from a side view. FIG. 11D schematically shows schematically shows a sectional view of the rotary unit of FIG. 11A. FIG. 11E schematically shows the rotary unit of FIG. 11A with implements from a front side view. FIG. 11F schematically shows the rotary unit of FIG. 11A with implements from a rear side view. FIG. 11G schematically shows the rotary unit of FIG. 11A with implements from a side view.

FIG. 12A schematically illustrates a rotary unit from a front side view according to one embodiment of the inven-

18

tion. FIG. 12B schematically shows the rotary unit of FIG. 12A from a rear side view. FIG. 12C schematically depicts the rotary unit of FIG. 12A from a side view. FIG. 12D schematically shows a gear structure of the rotary unit of FIG. 12A from a front side view. FIG. 12E schematically illustrates the gear structure of FIG. 12D from a rear side view. FIG. 12F schematically shows the gear structure of FIG. 12D from a side view.

FIG. 13A schematically illustrates a rotational component of a rotary unit from a front side view according to one embodiment of the invention. FIG. 13B schematically shows a sectional view of the rotational component of FIG. 13A. FIG. 13C schematically depicts the rotational component of FIG. 13A from a side view. FIG. 13D schematically shows a gear component used in the rotary unit referred to with respect to FIG. 13A from a front side view. FIG. 13E schematically illustrates the gear component of FIG. 13D from a side view.

FIG. 14A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 14B schematically depicts the rotary unit of FIG. 14A from a side view. FIG. 14C schematically shows the rotary unit of FIG. 14A from a rear side view. FIG. 14D schematically shows a sectional view of the gear structure of FIG. 14A.

FIG. 15A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 15B schematically shows the rotary unit of FIG. 15A from a rear side view. FIG. 15C schematically depicts the rotary unit of FIG. 15A from a side view. FIG. 15D schematically shows schematically shows a sectional view of the rotary unit of FIG. 15A.

FIG. 16A schematically illustrates a rotary unit from a front side view according to one embodiment of the invention. FIG. 16B schematically shows the rotary unit of FIG. 16A from a rear side view. FIG. 16C schematically depicts the rotary unit of FIG. 16A from a side view. FIG. 16D schematically shows schematically shows a sectional view of the rotary unit of FIG. 16A. FIG. 16E schematically illustrates a planetary gear component from a front side view according to one embodiment of the invention. FIG. 16F schematically illustrates the planetary gear component of FIG. 16E from a side view. FIG. 16G schematically shows an exploded side view of a gear structure according to one embodiment of the invention. FIG. 16H schematically depicts the gear structure of FIG. 16G from a side view. FIG. 16I schematically shows the gear structure of FIG. 16H from a rear side view. FIG. 16J schematically shows the gear structure of FIG. 16H from a front side view. FIG. 16K schematically illustrates a gear structure prior to assembly with another gear structure from a side view according to one embodiment of the invention. FIG. 16L schematically shows an assembly that includes two gear structures from a side view according to one embodiment of the invention. FIG. 16M schematically shows an exploded view of the rotary unit of FIG. 16A with the gear structure of FIG. 16G from a side view according to one embodiment of the invention. FIG. 16N schematically shows the rotary unit of FIG. 16A with the gear structure of FIG. 16G from a front side view. FIG. 16O schematically shows the rotary unit of FIG. 16A with the gear structure of FIG. 16G from a rear side view. FIG. 16P schematically shows the rotary unit of FIG. 16A with the gear structure of FIG. 16G from a side view. FIG. 16Q schematically shows a sectional view of the rotary unit of FIG. 16A with the gear structure of FIG. 16G.

FIG. 17A schematically depicts rotary units and a shaft from side elevational views prior to assembly according to one embodiment of the invention. FIG. 17B schematically

19

illustrates the rotary units and the shaft from FIG. 17A from side elevational views in an assembled format.

FIG. 18A schematically shows rotary units prior to assembly of a rotary mechanism from side views according to one embodiment of the invention. FIG. 18B schematically shows a partially assembled rotary mechanism with the rotary units of FIG. 18A from side views. FIG. 18C schematically illustrates a rotary mechanism that includes the rotary units of FIG. 18A from a side view.

FIG. 19A schematically illustrates a rotary mechanism that includes the rotary unit of FIG. 9A from a sectional view prior to assembly according to one embodiment of the invention. FIG. 19B schematically depicts the rotary mechanism of FIG. 19A from a sectional view following assembly. FIG. 19C schematically shows a portion of a rotary mechanism that includes the rotary unit of FIG. 9A with implements from a side view according to one embodiment of the invention.

FIG. 20A schematically illustrates a positioning component of a rotary mechanism from a side view according to one embodiment of the invention. FIG. 20B schematically depicts a portion of a rotary mechanism that includes the rotational component of FIG. 13A from a side view according to one embodiment of the invention. FIG. 20C schematically depicts a portion of a rotary mechanism that includes the rotational component of FIG. 13A and gear component of FIG. 13D from a side view according to one embodiment of the invention. FIG. 20D schematically shows the portion of the rotary mechanism of FIG. 20B from a sectional view. FIG. 20E schematically depicts the positioning component of FIG. 20A from a side view. FIG. 20F schematically shows the positioning component of FIG. 20A with a drive mechanism from a side view. FIG. 20G schematically illustrates a positioning component of a rotary mechanism from a side view according to one embodiment of the invention. FIG. 20H schematically illustrates a rotary mechanism that includes the rotational component of FIG. 13A from a side view according to one embodiment of the invention. FIG. 20I schematically shows the rotary mechanism of FIG. 20H from a sectional view. FIG. 20J schematically shows the rotary mechanism of FIG. 20H from a front side view. FIG. 20K schematically shows the rotary mechanism of FIG. 20H from a rear side view. FIG. 20L schematically depicts a portion of a drive mechanism from a side view according to one embodiment of the invention. FIG. 20M schematically depicts a portion of a drive mechanism from a side view according to one embodiment of the invention. FIG. 20N schematically depicts the portion of the drive mechanism of FIG. 20M without a motor from a side view. FIG. 20O schematically depicts the portion of the drive mechanism of FIG. 20M from a side view.

FIG. 21A schematically illustrates a rotary mechanism that includes the rotary unit of FIG. 14A from a sectional view prior to assembly according to one embodiment of the invention. FIG. 21B schematically depicts the rotary mechanism of FIG. 21A from a sectional view following assembly. FIG. 21C schematically shows the rotary of FIG. 21A from a side view. FIG. 21D schematically illustrates a rotary mechanism that includes the rotary unit of FIG. 14A with implements from a side view according to one embodiment of the invention. FIG. 21E schematically illustrates a rotary mechanism that includes the rotary unit of FIG. 14A with implements from a side view according to one embodiment of the invention.

FIG. 22A schematically illustrates a gear structure from the rotary unit of FIG. 14A prior to assembly with another gear structure from a side view according to one embodiment of the invention. FIG. 22B schematically shows an assembly of multiple gear structures from a side view according to one

20

embodiment of the invention. FIG. 22C schematically depicts the gear structure assembly of FIG. 22B from a rear side view. FIG. 22D schematically depicts the gear structure assembly of FIG. 22B from a front side view. FIG. 22E schematically shows a rotary mechanism that includes the gear structure assembly of FIG. 22B from a sectional view according to one embodiment of the invention. FIG. 22F schematically shows a rotary mechanism that includes the gear structure assembly of FIG. 22B from a side view according to one embodiment of the invention.

FIG. 23A schematically depicts a rotational mechanism from an exploded side view according to one embodiment of the invention. FIG. 23B schematically depicts the rotational mechanism from FIG. 23A from a side view. FIG. 23C schematically depicts the rotational mechanism from FIG. 23A from an exploded sectional view. FIG. 23D schematically depicts the rotational mechanism from FIG. 23A from a sectional side view. FIG. 23E schematically shows a portion of a drive mechanism component from a front side view according to one embodiment of the invention. FIG. 23F schematically shows the portion of the drive mechanism component of FIG. 23E from a rear side view. FIG. 23G schematically shows the portion of the drive mechanism component of FIG. 23E from a side view. FIG. 23H schematically shows the portion of the drive mechanism component of FIG. 23E from a sectional side view. FIG. 23I schematically shows an exploded side view of a gear structure according to one embodiment of the invention. FIG. 23J schematically depicts the gear structure from FIG. 23I from a rear side view. FIG. 23K schematically depicts the gear structure from FIG. 23I from a side view. FIG. 23L schematically depicts the gear structure from FIG. 23I from a front side view. FIG. 23M schematically shows an exploded side view of the drive mechanism component of FIG. 23E and the gear structure of FIG. 23I according to one embodiment of the invention. FIG. 23N schematically shows an exploded sectional side view of the drive mechanism component of FIG. 23E and the gear structure of FIG. 23I according to one embodiment of the invention. FIG. 23O schematically depicts the drive mechanism component of FIG. 23E and the gear structure of FIG. 23I from a side view. FIG. 23P schematically depicts the drive mechanism component of FIG. 23E and the gear structure of FIG. 23I from sectional side view. FIG. 23Q schematically depicts an exploded side view of the rotational mechanism from FIG. 23B and the portion of the drive mechanism component of FIG. 23E according to one embodiment of the invention. FIG. 23R schematically depicts an exploded side sectional view of the rotational mechanism from FIG. 23B and the portion of the drive mechanism component of FIG. 23E according to one embodiment of the invention. FIG. 23S schematically depicts a side view of the rotational mechanism from FIG. 23B and the portion of the drive mechanism component of FIG. 23E according to one embodiment of the invention. FIG. 23T schematically depicts a sectional side view of the rotational mechanism from FIG. 23B and the portion of the drive mechanism component of FIG. 23E according to one embodiment of the invention.

FIG. 24A schematically illustrates a rotor tiller that includes a rotary mechanism from a front elevational view according to one embodiment of the invention. FIG. 24B schematically illustrates the rotor tiller from FIG. 24A from a side elevational view.

FIG. 25A schematically illustrates a vehicle that includes rotary mechanisms from a side elevational view according to one embodiment of the invention. FIG. 25B schematically

21

illustrates a vehicle that includes rotary mechanisms from a side elevational view according to one embodiment of the invention.

FIG. 26A schematically shows a rotary mechanism of a hair cutting device from a side elevational view according to one embodiment of the invention. FIG. 26B schematically shows a removable structure of a hair cutting device from a side elevational view according to one embodiment of the invention. FIG. 26C schematically shows the rotary mechanism of FIG. 26A positioned in a housing of a hair cutting device from a partial cross-sectional view according to one embodiment of the invention. FIG. 26D schematically shows the rotary mechanism of FIG. 26A positioned in a housing of a hair cutting device prior to placing a removable structure in an opening of the housing from side elevational views according to one embodiment of the invention. FIG. 26E schematically shows the hair cutting device from FIG. 26D with the removable structure positioned in the opening of the housing from a side elevational view according to one embodiment of the invention. FIG. 26F schematically illustrates a person shaving facial hair using the hair cutting device from FIG. 26E from a side elevational view according to one embodiment of the invention. FIG. 26G schematically illustrates a cross-section of the hair cutting device from FIG. 26E.

FIG. 27A schematically illustrates a partially exploded view of a tooth brushing device according to one embodiment of the invention. FIG. 27B schematically shows an assembled tooth brushing device from FIG. 27A from a side view. FIG. 27C schematically depicts the tooth brushing device of FIG. 27B from a top side view. FIG. 27D schematically depicts a rotary mechanism from the tooth brushing device of FIG. 27B from a side view.

FIG. 28A schematically shows a rotary mechanism for a tooth brushing device from a side view according to one embodiment of the invention. FIG. 28B schematically depicts a toothbrush head component that includes the rotary mechanism of FIG. 28A from a side view according to one embodiment of the invention.

FIG. 29 schematically illustrates a cleaning device from a side view according to one embodiment of the invention.

FIG. 30A schematically illustrates an exploded view of a propulsion device according to one embodiment of the invention. FIG. 30B schematically shows the propulsion device of FIG. 30A from a partially exploded view. FIG. 30C schematically shows the propulsion device of FIG. 30A from a partially exploded view. FIG. 30D schematically illustrates the propulsion device of FIG. 30A from a side view. FIG. 30E schematically shows the propulsion device of FIG. 30A from a front side view. FIG. 30F schematically shows the propulsion device of FIG. 30A from a rear side view.

FIG. 31A schematically illustrates the propulsion device of FIG. 30A disposed within a housing from a front side view according to one embodiment of the invention. FIG. 31B schematically illustrates the propulsion device of FIG. 30A disposed within a housing from a rear side view according to one embodiment of the invention. FIG. 31C schematically illustrates the propulsion device of FIG. 30A disposed within a housing from a side view according to one embodiment of the invention. FIG. 31D schematically illustrates the propulsion device of FIG. 30A disposed within a housing from a partially sectional front side view according to one embodiment of the invention. FIG. 31E schematically illustrates the propulsion device of FIG. 30A disposed within a housing from a partially sectional side view according to one embodiment of the invention.

FIG. 32A schematically shows a propulsion device including rotary mechanisms from a partially exploded view

22

according to one embodiment of the invention. FIG. 32B schematically illustrates the propulsion device of FIG. 32A from a side view. FIG. 32C schematically shows the propulsion device of FIG. 32A from a front side view. FIG. 32D schematically shows the propulsion device of FIG. 32A from a rear side view.

FIG. 33A schematically shows a boat that includes propulsion devices from a side view according to one embodiment of the invention. FIG. 33B schematically illustrates the boat of FIG. 33A from a front side view.

FIG. 34A schematically shows an aircraft that includes propulsion devices from a front side view according to one embodiment of the invention. FIG. 34B schematically illustrates the aircraft of FIG. 34A from a side view.

FIG. 35A schematically shows a cleaning device that includes a rotary mechanism from a sectional view according to one embodiment of the invention. FIG. 35B schematically shows the cleaning device of FIG. 35A from a side view.

FIG. 36A schematically depicts a rotary mechanism from a top view according to one embodiment of the invention. FIG. 36B schematically illustrates the rotary mechanism of FIG. 36A from a side view. FIG. 36C schematically illustrates the rotary mechanism of FIG. 36A from a front side view. FIG. 36D schematically illustrates the rotary mechanism of FIG. 36A from a rear side view. FIG. 36E schematically shows a head component of a cleaning device that includes the rotary mechanism of FIG. 36A from an exploded side view. FIG. 36F schematically shows the head component of FIG. 36A from a sectional view. FIG. 36G schematically shows a cleaning device that includes the head component of FIG. 36A from a side view according to one embodiment of the invention.

FIG. 37 schematically shows a rotary mechanism from a top side view according to one embodiment of the invention.

FIG. 38 schematically shows a cleaning device that includes a rotary mechanism from a side view according to one embodiment of the invention.

FIG. 39 schematically shows a cleaning device that includes the rotary mechanism of FIG. 37A from a side view according to one embodiment of the invention.

FIG. 40A schematically shows a cleaning device that includes the rotary mechanism of FIG. 37A and removable fluid containers prior to assembly from a side view according to one embodiment of the invention. FIG. 40B schematically shows the cleaning device of FIG. 40A following assembly from a side view.

FIGS. 41 A-Q schematically show a cleaning device or implement, a cleaning material component, or components thereof from various views according to one exemplary embodiment of the invention. FIG. 41A schematically illustrates a head component of a cleaning device that includes the rotary mechanism of FIG. 21E from a side view according to one embodiment of the invention. FIG. 41B schematically shows the head component of the cleaning device of FIG. 41A including a cleaning material cartridge from a side view. FIG. 41C schematically depicts the cleaning device of FIG. 41A with an exemplary retaining component in a closed position from a side view. FIG. 41D schematically depicts the cleaning device of FIG. 41A with components of an exemplary fluid handling mechanism from a side view. FIG. 41E schematically shows a cleaning material cartridge being inserted into the cleaning material support component of the cleaning device of FIG. 41A from a side view. FIG. 41F schematically shows a cleaning material cartridge operably engaging a conveyance mechanism of the cleaning device of FIG. 41A from a top side view. FIG. 41G schematically depicts the head component of the cleaning device of FIG. 41A from a sec-

23

tional top side view. FIG. 41H schematically depicts a cleaning material cartridge of the cleaning device of FIG. 41A from a side view. FIG. 41I schematically depicts a cleaning material cartridge of the cleaning device of FIG. 41A from a side view. FIG. 41J schematically depicts a cleaning material cartridge of the cleaning device of FIG. 41A from a top side view. FIG. 41K schematically shows a cleaning material cartridge of the cleaning device of FIG. 41A from a bottom side view. FIG. 41L schematically depicts a cleaning material cartridge of the cleaning device of FIG. 41A from a side view. FIG. 41M schematically shows a sectional view of a cleaning material support component of a cleaning material cartridge according to one embodiment of the invention. FIG. 41N schematically shows the head component of a cleaning device of FIG. 41A with a handle and a removable fluid container being positioned relative to the cleaning device from a side view. FIG. 41O schematically shows the head component of a cleaning device of FIG. 41A with a handle from a side view. FIG. 41P schematically shows the cleaning device of FIG. 41O with a handle from a front side view. FIG. 41Q schematically depicts the head component of the cleaning device of FIG. 41A including an elevational element from a side view.

FIGS. 42 A-G schematically illustrate rotary units or components thereof from various views according to one exemplary embodiment of the invention. FIG. 42A schematically shows a rotational component from a front side view according to one embodiment of the invention. FIG. 42B schematically shows the rotational component from FIG. 42A from a side sectional view. FIG. 42C schematically depicts the rotational component from FIG. 42A from a side view. FIG. 42D schematically depicts the rotational component from FIG. 42A from a side view with a surface including implements. FIG. 42E schematically shows the rotational component from FIG. 42D from a front side view. FIG. 42F schematically shows a rotary unit that includes the rotational component from FIG. 42A and first and third gear components from a front side view according to one exemplary embodiment of the invention. FIG. 42G schematically shows a rotary unit that includes the rotational component from FIG. 42A and a second gear component from a front side view according to one exemplary embodiment of the invention.

FIGS. 43 A-I schematically illustrate a rotary mechanism or components thereof from various views according to one exemplary embodiment of the invention. FIG. 43A schematically shows a rotary mechanism from a front side view according to one embodiment of the invention. FIG. 43B schematically shows rotational components positioned relative to one another from a cross-sectional view according to one embodiment of the invention. FIG. 43C schematically illustrates gear components of a counter-rotational mechanism operably engaging a drive mechanism component from a side view according to one embodiment of the invention. FIG. 43D schematically illustrates gear components of a counter-rotational mechanism operably engaging a drive mechanism component from a side view according to one embodiment of the invention. FIG. 43E schematically shows the gear and drive mechanism components from FIGS. 43 C and D positioned relative to one another from a side view. FIG. 43F schematically shows the rotary mechanism from FIG. 43A from a side view. FIG. 43G schematically depicts the rotary mechanism from FIG. 43A from a side sectional view. FIG. 43H schematically depicts the rotary mechanism from FIG. 43G from a side sectional view with an exemplary motor. FIG. 43I schematically shows the rotary mechanism from FIG. 43H from a side view with rotational components including implements.

24

FIGS. 44 A-C schematically illustrate a rotary mechanism or components thereof from various views according to one exemplary embodiment of the invention. FIG. 44A schematically shows portions of a rotational component prior to assembly from a side view. FIG. 44B schematically depicts a rotary mechanism that includes the rotational component from FIG. 44A prior to assembly from a front side view. FIG. 44C schematically depicts the rotary mechanism from FIG. 44B from a side view.

FIGS. 45 A and B schematically show gear and drive mechanism components prior to and following assembly, respectively, according to one exemplary embodiment of the invention.

FIGS. 46 A and B schematically show gear and drive mechanism components prior to and following assembly, respectively, according to one exemplary embodiment of the invention.

FIG. 47A schematically shows a detailed front side view of a shaft receiving area according to one embodiment of the invention.

FIG. 47B schematically shows a detailed front side view of a drive mechanism portion configured to be received by the one drive mechanism component area from FIG. 47A according to one embodiment of the invention.

FIG. 48 schematically shows a rotary mechanism prior to assembly from a side view according to one embodiment of the invention.

FIGS. 49 A-C schematically depict a tooth brushing device or components thereof from various views according to one exemplary embodiment of the invention. FIG. 49A schematically shows a rotary mechanism and drive mechanism components from a side view according to one exemplary embodiment of the invention. FIG. 49B schematically illustrates a tooth brushing device that includes the rotary mechanism and drive mechanism components from FIG. 49A from a partially transparent side view. FIG. 49C schematically shows a tooth brushing device that includes the rotary mechanism and drive mechanism components from FIG. 49A from a side view.

FIGS. 50 A-E schematically show a hair cutting device or components thereof from various views according to one exemplary embodiment of the invention. FIG. 50A schematically depicts a hair cutting device from a partially transparent side view according to one exemplary embodiment of the invention. FIG. 50B schematically depicts the hair cutting device from FIG. 50A prior to assembly from a side view. FIG. 50C schematically depicts the hair cutting device from FIG. 50B following assembly from a side view. FIG. 50D schematically shows a rotational component that includes cutting implements from the hair cutting device from FIG. 50A from a front side view. FIG. 50E schematically shows the rotational component from FIG. 50D from a side view.

FIGS. 51 A-F schematically show a rotary mechanism or components thereof from various views according to one exemplary embodiment of the invention. FIG. 51A schematically illustrates gear and drive mechanism components of a rotary mechanism prior to assembly from a side view. FIG. 51B schematically illustrates gear and drive mechanism components of a rotary mechanism from a side view. FIG. 51C schematically illustrates the gear and drive mechanism components from FIG. 51B positioned relative to rotational components from a sectional side view. FIG. 51D schematically shows the rotary mechanism from FIG. 51C from a front side view. FIG. 51E schematically shows the rotary mechanism from FIG. 51C from a side view. FIG. 51F schematically

25

shows a drive mechanism positioning component from a front side view according to one exemplary embodiment of the invention.

FIGS. 52 A and B schematically show a tooth brushing device or components thereof from various views according to one exemplary embodiment of the invention. FIG. 52A schematically depicts a tooth brushing device from a partially transparent side view according to one exemplary embodiment of the invention. FIG. 50B schematically depicts the tooth brushing device from FIG. 52A from a side view.

DETAILED DESCRIPTION

I. Introduction

Before describing the invention in detail, it is to be understood that this invention is not limited to particular methods, rotary units, rotary mechanisms, devices, or systems, which can vary. As used in this specification and the appended claims, the singular forms “a,” “an,” and “the” also include plural referents unless the context clearly provides otherwise. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to be limiting. Further, unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention pertains. In describing and claiming the invention, the following terminology, and grammatical variants thereof, will be used in accordance with the definitions set forth below.

The term “coaxially positioned” refers to objects that are positioned relative to one another such that they can rotate about a substantially coincident axis.

The term “fixed position” refers to objects that are positioned relative to one another such that they do not move separately from one another. In some embodiments, for example, gear components (e.g., sun gear components) are attached (e.g., integrally fabricated, bonded, welded, adhered, or the like) to rotational components, such that when the rotational components move in one direction, the gear components move in the same direction as the rotational components.

The term “counter-rotate” or “contra-rotate” refers to objects that rotate in opposite directions relative to one another. In some embodiments, for example, rotary mechanisms include rotational components that are configured to rotate in opposite directions.

The term “communicate” refers to the direct or indirect transfer or transmission, and/or capability of directly or indirectly transferring or transmitting, something at least from one thing to another thing. In some embodiments, for example, devices include housings having openings through which hair, finger nails, or the like can be transferred to contact implements within housing cavities of the devices.

The invention relates to rotary units and rotary mechanisms that are suitable for use in numerous applications. Rotary units typically include rotational components that are configured to rotate. In some embodiments, for example, multiple rotary units are assembled in rotary mechanisms such that neighboring pairs of rotational components counter-rotate or contra-rotate relative to one another during operation of the rotary mechanisms. Rotational components generally include one or more implements that are structured to perform or effect one or more types of work as the rotational components rotate relative to one another in a given rotary mechanism. In certain embodiments, implements are configured to rotate and/or to effect the movement of other components as rota-

26

tional components rotate. The representative embodiments described herein are intended to illustrate, but not to limit, the invention. Essentially any combination of components or portions thereof described herein are optionally utilized or adapted for use together in certain embodiments.

II. Exemplary Rotary Units

FIGS. 1 A-H schematically show a rotary unit or components thereof according to one embodiment of the invention. As shown, rotary unit 100 includes rotational component 102, which includes first gear component 104 disposed on a first side of rotational component 102 (e.g., in an inner region of the first side) and second gear component 106 disposed on a second side of rotational component 102 (e.g., in an outer region of the second side). As shown, the first and second sides substantially oppose one another. Gear components used with the rotary units, rotary mechanisms, and other applications of the invention typically include gear teeth. Any operable gear tooth configuration and/or type are optionally used in the rotary units, rotary mechanisms and applications of the invention. Second gear component 106 substantially defines gear structure receiving area 108, which is configured to receive gear structure 110. Gear structure 110 includes support component 112 and third gear components 114. Third gear components 114 are configured to operably engage second gear component 106 such that when third gear components 114 rotate in a first direction, second gear component 106 and rotational component 102 also rotate the first direction. Third gear components 114 are configured to operably engage other gear components, such as a first gear component of another rotary unit such that when the other gear components rotate in a second direction, third gear components 114, second gear component 106, and rotational component 102 all rotate in the first direction. Rotary unit 100 also includes retaining mechanism 116 (shown as a wall or lip in this exemplary embodiment) that is structured to retain gear structure 110 at least partially in gear structure receiving area 108. As further shown in FIG. 1I, for example, in some embodiments during rotary unit assembly retaining mechanism 116 is attached to rotational component 102, once gear structure 110 is positioned in gear structure receiving area 108, via attachment components 118 (e.g., which clip into corresponding notches (not within view) in rotational component 102 in this representative embodiment).

Rotary unit 100 also includes implements 120 shown as beads that can be used, for example, as part of a massaging device or the like. Essentially any implement (e.g., type(s) and/or number on a given rotational component, etc.) is optionally adapted for use with the rotary units of the present invention, e.g., depending on the intended application of a given rotary unit. Representative implements that are optionally used include one or more of, e.g., a blade, a razor, a prong, a peg, a claw, a tine, a chain, a stake, a column, a pillar, an arch, a bracket, a gear component, a bristle, a plume, an abrasive component, an elastomeric component, a nail filing component, a nail buffing component, a hair cutting component, a massaging component, a post, or the like. Some exemplary implements 200-210 are also illustrated from side elevational views in, e.g., FIGS. 2 A-F.

In addition, rotary unit 100 also includes drive mechanism component receiving area 122 (shown as a hole disposed through rotational component 102) that is configured to receive a drive mechanism component, such as a drive shaft or a portion thereof. Other exemplary drive mechanism components are described herein or otherwise known in the art.

FIGS. 3 A-G schematically illustrate a rotary unit or components thereof according to one embodiment of the invention. As shown, rotary unit **300** includes rotational component **302**, which includes first gear component **304** extending from a first side, and second gear component **306** on a second side and substantially defining gear structure receiving area **308**. Rotary unit **300** also includes gear structure **310**, which includes third gear components **312** rotatably coupled to support component **314**. As also shown, gear structure **310** includes hole **316** that is structured to align with drive mechanism component receiving area **318** of rotational component **302**, e.g., to receive a drive mechanism component, such as a drive shaft about which gear structure **310** and rotational component **302** rotate.

Rotary unit **300** also includes a retaining mechanism that is configured to retain gear structure **310** in position relative to rotational component **302** such that the components can operably engage one another during operation. The retaining mechanism of rotary unit **300** includes groove or track **320** disposed approximately around gear structure receiving area **308** in rotational component **302**. In addition, the retaining mechanism also includes projections **322** of gear structure **310** that insert into groove or track **320** such that gear structure **310** is retained and rotates within gear structure receiving area **308**.

In some embodiments, the rotational components of the rotary units of the invention include implements that are configured to effect the movement of one or more other components (e.g., propeller components or the like) when the rotational components rotate and the implements operably engage the other components. To illustrate, rotational component **302** of rotary unit **300** also includes gear component **324** that is configured to operably engage other gear components of other components, e.g., to effect rotation of those components when rotational component **302** rotates.

FIGS. 4 A-G schematically show another exemplary embodiment of a rotary unit of the invention. As shown, rotary unit **400** includes rotational component **402** that includes first and second surfaces that substantially oppose one another. First gear component **404** is disposed on the first surface of rotational component **402** and is configured to operably engage third gear components of another rotary unit. Second gear component **406** is disposed on the second surface of rotational component **402** and substantially defines gear structure receiving area or cavity **408**.

Rotary unit **400** also include gear structure **410**, which includes support structure **412** and third gear components **414** rotatably coupled to support structure **412**. Rotary unit **400** also includes a retaining mechanism formed, in part, by groove or track **416** formed in rotational component **402**. Circular projection **418** disposed on support structure **412** of gear structure **410** is configured to fit within groove or track **416** such that gear structure **410** is retained, yet permitted to rotate, within gear structure receiving area **408**. As also shown, rotary unit **400** also includes implements **420** (shown as blades) extending from a surface of rotational component **402**.

FIGS. 5 A and B schematically illustrate a rotary unit according to another exemplary embodiment of the invention. As shown, rotary unit **500** includes rotational component **502**. First gear component **504** extends from a first side of rotational component **502**, while gear structure **506** engages a second gear component in a gear structure receiving area on a second side of rotational component **502** and partially extends from the gear structure receiving area. Gear structure includes third gear components **508** rotatably coupled to support structure **510**. Rotary unit **500** also includes a retaining

mechanism formed, in part, by groove or track **512** formed in the gear structure receiving area of rotational component **502**. Circular projection **514** disposed on support structure **510** of gear structure **506** is configured to fit within groove or track **512** such that gear structure **506** is retained, yet permitted to rotate, within the gear structure receiving area of rotational component **502**. First gear component **504** is configured to engage one or more third gear components of another rotary unit. Third gear components **508** are configured to engage the second gear component in the gear structure receiving area and a first gear component of another rotary unit.

FIGS. 6 A-G schematically show a rotary unit or components thereof according to another representative embodiment of the invention. As shown, rotary unit **600** includes rotational component **602**. Rotational component **602** includes first gear component **604** on a first side and second gear component **606** on a second side. Second gear component **606** substantially defines a gear structure receiving area of rotational component **602**. Rotary unit **600** also includes gear structure **608** disposed within the gear structure receiving area. Gear structure **608** includes third gear components **610** rotatably coupled to support component **612**. Third gear components **610** are configured to operably engage second gear component **606** of rotational component **602** and the first gear component of another rotary unit or another gear component, such as a component of a drive mechanism or the like. Gear structure **608** also includes hole or aperture **614**, which is structured to align with drive mechanism component receiving area **616** of rotational component **602**, e.g., to receive a drive mechanism component, such as a drive shaft about which gear structure **608** and rotational component **602** rotate. Rotary unit **600** also includes a retaining mechanism that is configured to retain and permit gear structure **608** to rotate within the gear structure receiving area of rotational component **602**. In particular, support component **612** of gear structure **608** includes partially circular indentation **618** and rotational component **602** comprises projection **620** (e.g., an elevated circular track or the like). Projection **620** is configured to at least partially fit and move within partially circular indentation **618** to retain gear structure **608** at least partially within the gear structure receiving area when second gear component **606** and third gear components **610** operably engage one another. In some embodiments, gear structures comprise projections, such as projection **620** and rotational components comprise the substantially or partially circular indentation (e.g., a circular track or groove structured to receive the projection).

Rotary unit **600** also includes implements **622** that are rotatably coupled to rotational component **602**. As shown, rotatably coupled implements **622** include gear components **624** that are configured to operably engage a corresponding gear component on a neighboring rotary unit when the neighboring rotary unit is disposed suitably proximal to rotary unit **600**. In these embodiments, during operation, as neighboring rotary units counter-rotate relative to one another, rotatably coupled implements, such as implements **622** (e.g., shown as bristles suitable for a toothbrush, household cleaning device, or the like) also rotate. To further illustrate, rotary unit **600** includes gear component **626** that is configured to operably engage rotatably coupled implements disposed on a neighboring rotary unit.

FIGS. 7 A-C schematically show a rotary unit according to one embodiment of the invention. As shown, rotary unit **700** includes rotational component **702**, which includes first gear component **704** on a first side. Rotary unit **700** also includes a gear structure **706** disposed and able to rotate within a gear structure receiving area rotational component **702**. Lip or

wall **708** retains gear structure **706** in the gear structure receiving area. Rotary unit **700** also includes alignment components that are structured to align rotary units relative to one another, e.g., in a given device or other application. In particular, the first side of rotational component **702** includes circular groove **710**, while the second side of rotational component **702** includes circular ridge **712**. Circular groove **710** is configured to receive a circular ridge (e.g., circular ridge **812**) of another rotary unit (e.g., rotary unit **800**), which circular ridge is configured to rotate within circular groove **710**. In contrast, circular ridge **712** is configured to fit and rotate within a circular groove (e.g., circular groove **810**) of another rotary unit (e.g., rotary unit **800**). In some embodiments, the first side of rotational component **702** includes circular ridge **712**, while the second side of rotational component **702** includes circular groove **710**.

Rotary unit **700** also include drive mechanism component receiving area **714** that is configured to receive a drive mechanism component (e.g., drive mechanism component **816** (shown as a drive shaft) of rotary unit **800**). Rotational component **702** is configured to rotate about a drive mechanism component (e.g., drive mechanism component **816** of rotary unit **800**), while first gear component **704** operably engages a gear component (e.g., a gear component of a gear structure) of another rotary unit (e.g., a rotary unit, such as a rotary unit **800**) and gear components of gear structure **706** operably engage another gear component (e.g., a first gear component) of yet another rotary unit (e.g., another rotary unit, such as another rotary unit **800**). As also shown, a surface of rotational component **702** also includes multiple implements **716** (shown as razors or cutting edges) that are optionally used in hair cutting devices or other applications.

FIGS. **8A-C** schematically show a rotary unit according to one embodiment of the invention. As shown, rotary unit **800** includes rotational component **802**, which includes first gear component **804** on a first side. Rotary unit **800** also includes a gear structure **806** disposed and able to rotate within a gear structure receiving area rotational component **802**. Lip or wall **808** retains gear structure **806** in the gear structure receiving area. Rotary unit **800** also includes alignment components that are structured to align rotary units relative to one another, e.g., in a given device or other application. In particular, the first side of rotational component **802** includes circular groove **810**, while the second side of rotational component **802** includes circular ridge **812**. Circular groove **810** is configured to receive a circular ridge (e.g., circular ridge **712**) of another rotary unit (e.g., rotary unit **700**), which circular ridge is configured to rotate within circular groove **810**. In contrast, circular ridge **812** is configured to fit and rotate within a circular groove (e.g., circular groove **710**) of another rotary unit (e.g., rotary unit **700**). In some embodiments, the first side of rotational component **802** includes circular ridge **812**, while the second side of rotational component **802** includes circular groove **810**.

Rotary unit **800** also include drive mechanism component receiving area **814** that is configured to receive a drive mechanism component (e.g., drive mechanism component **816** of a rotary unit **800**). In the embodiment shown, drive mechanism component receiving area **814** includes a female threaded region that is configured to receive a male threaded region of drive mechanism component **816** of another rotary unit **800**. As described above, another rotary unit (such as a rotary unit **700**) is configured to fit between two rotary units **800** and rotate around a drive mechanism component **816** of one of the rotary units **800**. As also shown, a surface of rotational com-

ponent **802** also includes multiple implements **818** (shown as razors or cutting edges) that are optionally used in hair cutting devices or other applications.

FIGS. **9A-L** schematically depict an exemplary rotary unit or components thereof according to one embodiment of the invention. As shown, rotary unit **900** includes rotational component **902** that is configured to rotate around rotational axis **904**. Rotational component **902** includes first surface **906** and second surface **908**. First surface **906** includes gear component **910** (e.g., a sun gear component, etc.) that is configured to operably engage one or more gear components of at least a second rotational component (not shown) when rotational component **902** is disposed proximal to the second rotational component such that when the rotational component **902** rotates in a first direction, the second rotational component rotates in a second direction. In addition, second surface **908** comprises gear component **912** (e.g., a ring gear component, etc.) that is configured to operably engage one or more gear components (via gear components **914**) of a third rotational (not shown) component when rotational component **902** is disposed proximal to the third rotational component such that when rotational component **902** rotates in the first direction, the second rotational component rotates in the second direction.

Gear structure **915** includes support component **917** and gear components **914** (e.g., planetary gear components or the like), which are rotatably coupled to support component **917**. Support component **917** of gear structure **915** also includes friction reducing materials **919** (shown as elevated or pointed surface features) to reduce friction as rotational component **902** rotates relative to support component **917**. As also shown in, for example, FIGS. **9J-L**, surface **916** of the rotational component **902** comprises implement **918** (shown as a plurality of bristles), which surface **916** is configured to rotate substantially non-perpendicular to rotational axis **904**. In this embodiment, for example, surface **916** of rotational component **902** is configured to rotate substantially parallel to rotational axis **904**.

Rotary unit **900** also includes friction reducing materials **920** (shown as roller balls) disposed on first surface **906** of rotational component **902** to reduce friction as rotational component **902** rotates relative to another rotational component. In the embodiments in which friction reducing materials are utilized, essentially any friction reducing material is optionally adapted for use with the rotary units of the invention. Other exemplary embodiments include, for example, coatings (e.g., TEFLON®, etc.), lubricants, surface features, and/or the like. Rotational mechanisms typically include one or more rotary units **900**. Exemplary rotational mechanisms are described further herein.

As further shown in FIG. **9I**, for example, in some embodiments during rotary unit assembly retaining mechanism **922** is attached to another portion of rotational component **902**, once gear structure **915** is positioned in a gear structure receiving area, via attachment components **924** (e.g., which clip into corresponding notches (not within view) in the portion of the rotational component that includes retaining mechanism **922** in this representative embodiment).

In addition, rotary unit **900** also includes drive mechanism component receiving area **925** (shown as a hole disposed through rotational component **902**) that is configured to receive a drive mechanism component, such as a drive shaft or a portion thereof. Other exemplary drive mechanism components are described herein or otherwise known in the art.

FIGS. **10A-M** schematically depict an exemplary rotary unit or components thereof according to one embodiment of the invention. As shown, rotary unit **1000** includes rotational

31

component **1002** that is configured to rotate around rotational axis **1004**. Rotational component **1002** includes first surface **1006** and second surface **1008**. First surface **1006** includes gear component **1010** (e.g., a sun gear component, etc.) that is configured to operably engage one or more gear components of at least a second rotational component (not shown) when rotational component **1002** is disposed proximal to the second rotational component such that when the rotational component **1002** rotates in a first direction, the second rotational component rotates in a second direction. In addition, second surface **1008** comprises gear component **1012** (e.g., a ring gear component, etc.) that is configured to operably engage one or more gear components (via gear components **1014**) of a third rotational (not shown) component when rotational component **1002** is disposed proximal to the third rotational component such that when rotational component **1002** rotates in the first direction, the third rotational component rotates in the second direction (e.g., in the same direction as the second rotational component).

Gear structure **1015** includes support component **1017** and gear components **1014** (e.g., planetary gear components or the like), which are rotatably coupled to support component **1017**. Support component **1017** of gear structure **1015** also includes friction reducing materials **1019** (shown as elevated or pointed surface features) to reduce friction as rotational component **1002** rotates relative to support component **1017**. As also shown in, for example, FIGS. **10K-M**, surface **1016** of the rotational component **1002** comprises implement **1018** (shown as a plurality of bristles), which surface **1016** is configured to rotate substantially non-perpendicular to rotational axis **1004**. In this embodiment, for example, surface **1016** of rotational component **1002** is configured to rotate substantially parallel to rotational axis **1004**.

Rotary unit **1000** also includes friction reducing materials **1020** (shown as elevated surface features) disposed on first surface **1006** of rotational component **1002** to reduce friction as rotational component **1002** rotates relative to another rotational component. In the embodiments in which friction reducing materials are utilized, essentially any friction reducing material is optionally adapted for use with the rotary units of the invention. Other exemplary embodiments include, for example, coatings (e.g., TEFLON®, etc.), lubricants, surface features, and/or the like. In some embodiments of the rotary units of the invention, friction reducing materials are not utilized. Rotational mechanisms typically include one or more rotary units **1000**. Exemplary rotational or rotary mechanisms are described further herein.

In addition, rotary unit **1000** also includes drive mechanism component receiving area **1024** (shown as a hole disposed through rotational component **1002**) that is configured to receive a drive mechanism component, such as a drive shaft or a portion thereof. Other exemplary drive mechanism components are described herein or otherwise known in the art.

To further illustrate, FIGS. **11A-G** schematically show a rotary unit or components thereof according to an exemplary embodiment of the invention. As shown, rotary unit **1100** includes rotational component **1102** that is configured to rotate around rotational axis **1104**. Rotational component **1102** includes first surface **1106** and second surface **1108**. First surface **1106** includes gear component **1110** (e.g., a sun gear component, etc.) that is configured to operably engage one or more gear components (via gear components **1114**) of at least a second rotational component (not shown) when rotational component **1102** is disposed proximal to the second rotational component such that when the rotational component **1102** rotates in a first direction, the second rotational component rotates in a second direction. In addition, second

32

surface **1108** comprises gear component **1112** (e.g., a ring gear component, etc.) that is configured to operably engage one or more gear components of a third rotational (not shown) component when rotational component **1102** is disposed proximal to the third rotational component such that when rotational component **1102** rotates in the first direction, the third rotational component rotates in the second direction (e.g., in the same direction as the second rotational component).

Gear structure **1115** includes support component **1117** and gear components **1114** (e.g., planetary gear components or the like), which are rotatably coupled to support component **1117**. Support component **1117** of gear structure **1115** also includes friction reducing materials **1119** (shown as elevated or pointed surface features) to reduce friction as rotational component **1102** rotates relative to support component **1117**. As also shown in, for example, FIGS. **11E-G**, surface **1116** of the rotational component **1102** comprises implement **1118** (shown as a plurality of bristles in this exemplary embodiment), which surface **1116** is configured to rotate substantially non-perpendicular to rotational axis **1104**. In this embodiment, for example, surface **1116** of rotational component **1102** is configured to rotate substantially parallel to rotational axis **1104**. Rotational mechanisms typically include one or more rotary units **1100**. Exemplary rotational mechanisms are described further herein.

In addition, rotary unit **1100** also includes drive mechanism component receiving area **1124** (shown as a hole disposed through rotational component **1102**) that is configured to receive a drive mechanism component, such as a drive shaft or a portion thereof. Other exemplary drive mechanism components are described herein or otherwise known in the art.

FIGS. **12A-F** schematically show a rotary unit or components thereof according to an exemplary embodiment of the invention. As shown, rotary unit **1200** includes rotational component **1202** that includes gear component **1210** (e.g., a sun gear component, etc.) that is configured to operably engage one or more gear components of at least a second rotational component (not shown) when rotational component **1202** is disposed proximal to the second rotational component such that when the rotational component **1202** rotates in a first direction, the second rotational component rotates in a second direction. In addition, rotational component **1202** comprises gear component **1212** (e.g., a ring gear component, etc.) that is configured to operably engage one or more gear components (via gear components **1214**) of a third rotational (not shown) component when rotational component **1202** is disposed proximal to the third rotational component such that when rotational component **1202** rotates in the first direction, the third rotational component rotates in the second direction. Rotational component **1202** is structured similar to rotational component **1002** described herein, but further includes recessed area **1203**, which is described below.

Gear structure **1215** includes support component **1217** and gear components **1214** (e.g., planetary gear components or the like), which are rotatably coupled to support component **1217**. Support component **1217** of gear structure **1215** also includes friction reducing materials **1219** (shown as elevated or pointed surface features) to reduce friction as rotational component **1202** rotates relative to support component **1217**. As also shown, gear structure **1215** also includes retaining features **1220** that are structured to fit and move within recessed area **1203** when gear structure **1215** is disposed in the gear structure receiving area of rotational component **1202**. Retaining features **1220** further align and retain gear structure **1215** relative to rotational component **1202**. In some embodiments, retaining features **1220** are not included.

Although not shown, rotary unit **1200** also typically includes one or more implements. Rotational mechanisms typically include one or more rotary units **1200**. Exemplary rotational mechanisms are described further herein.

In addition, rotary unit **1200** also includes drive mechanism component receiving area **1224** (shown as a hole disposed through rotational component **1202**) that is configured to receive a drive mechanism component, such as a drive shaft or a portion thereof. Other exemplary drive mechanism components are described herein or otherwise known in the art.

FIGS. **13A-E** schematically show components of rotary unit according to one exemplary embodiment of the invention. As shown, the rotary unit includes rotational component **1302** and gear component **1304** (e.g., a planetary gear component or the like). Although not shown, rotational component **1302** typically includes one or more implements (e.g., gear components, bristles, prongs, blades, etc.). Rotational component **1302** includes gear component **1310** (e.g., a sun gear component, etc.) that is configured to operably engage or mesh with gear component **1304**. Rotational mechanisms that include these components are described further herein.

FIGS. **14A-D** schematically show a rotary unit or components thereof according to an exemplary embodiment of the invention. As shown, rotary unit **1400** includes rotational component **1402** that includes gear component **1410** (e.g., a sun gear component, etc.), gear component **1412** (e.g., a ring gear component, etc.), and gear structure receiving area **1413**. Gear component **1410** substantially fixedly extends from first surface **1406** of rotational component **1402**. Gear component **1410** is configured to operably engage or mesh with one or more other gear components of another rotary unit when gear component **1410** is disposed proximal to the other gear components. Gear component **1412** substantially fixedly extends from second surface **1408** of rotational component **1402**. Gear component **1412** communicates with gear structure receiving area **1413**. Gear structure receiving area **1413** is configured to receive gear structure **1415**.

Gear structure **1415** includes support component **1417** and gear components **1414** (e.g., planetary gear components or the like), which are rotatably coupled to support component **1417**. Gear components **1414** are configured to operably engage or mesh with one or more other gear components when gear components **1414** are disposed proximal to the other gear components. Rotational component **1402** is configured to rotate relative to support component **1417**, which support component **1417** is substantially fixedly positioned when rotational component **1402** rotates relative to support component **1417**. Gear components **1414** are configured to rotate relative to rotational component **1402**. Gear structures that include support components **1417** are described further herein. Although not shown, rotary unit **1400** also typically includes one or more implements. Rotational mechanisms typically include one or more rotary units **1400**. Exemplary rotational mechanisms are described further herein.

FIGS. **15A-D** schematically illustrate a rotary unit according to one embodiment of the invention. As shown, rotary unit **1500** includes rotational component **1502** that includes first sun gear component **1504** and second sun gear component **1506** on first and second surfaces, respectively, of rotational component **1502**, which substantially oppose one another. First sun gear component **1504** is configured to operably engage one or more gear components of at least a second rotational component (not shown) when rotational component **1502** is disposed proximal to the second rotational component such that when rotational component **1502** rotates in a first direction, the second rotational component rotates in a second direction. Second sun gear component **1506** is con-

figured to operably engage one or more gear components of at least a third rotational component (not shown) when rotational component **1502** is disposed proximal to the third rotational component such that when rotational component **1502** rotates in the first direction, the third rotational component rotates in the second direction. Exemplary gears that are optionally adapted for use with the rotary units, rotational mechanisms, and related applications of the invention are also described in, e.g., Dudley, *Handbook of Practical Gear Design (Mechanical Engineering Series)*, CRC Press, 1st Ed. (1994) and Litvin and Fuentes, *Gear Geometry and Applied Theory*, Cambridge University Press; 2nd Ed. (2004), which are both incorporated herein in their entirety for all purposes.

Rotary unit **1500** also includes hole **1508** disposed through rotational component **1502**. Hole **1508** is configured to receive, e.g., a drive mechanism component (e.g., an axle, a shaft, a gear structure component, etc.) or a support component such that rotational component **1502** can rotate around the drive mechanism component, the support component, or the like. Rotational component **1502** also includes friction reducing materials **1510** (shown as elevated or pointed surface features) to reduce friction as rotational component **1502** rotates relative to, e.g., other rotational component. In addition, rotational component **1502** also include implements **1512** on a surface of rotational component **1502** that is configured to rotate substantially non-perpendicular to a rotational axis of rotary unit **1500**. Essentially any implement is optionally adapted for use with rotary unit **1500**, including the exemplary implements described herein. Rotary unit **1500** is typically included in a rotational mechanism, a device or the like. Exemplary rotational mechanisms that include rotary unit **1500** are described herein. In addition, representative devices that are optionally adapted to include rotary unit **1500** are also described herein.

FIGS. **16A-Q** schematically illustrate a rotary unit or components thereof according to one embodiment of the invention. As shown, rotary unit **1600** includes rotational component **1602** that includes first ring gear component **1604** and second ring gear component **1606** on first and second surfaces, respectively, of rotational component **1602**, which substantially oppose one another. First ring gear component **1604** is configured to operably engage one or more gear components of at least a second rotational component (not shown) when rotational component **1602** is disposed proximal to the second rotational component such that when rotational component **1602** rotates in a first direction, the second rotational component rotates in a second direction. Second ring gear component **1606** is configured to operably engage one or more gear components of at least a third rotational component (not shown) when rotational component **1602** is disposed proximal to the third rotational component such that when rotational component **1602** rotates in the first direction, the third rotational component rotates in the second direction.

Rotary unit **1600** also includes hole **1608** disposed through rotational component **1602**. Hole **1608** is configured to receive, e.g., a drive mechanism component (e.g., an axle, a shaft, a gear structure component, etc.) or a support component such that rotational component **1602** can rotate around the drive mechanism component, the support component, or the like. Exemplary drive mechanism components and support components are described herein. Although not shown, rotational component **1602** optionally also includes friction reducing materials (e.g., elevated or pointed surface features, surface coatings, roller balls, etc.) to reduce friction as rotational component **1602** rotates relative to, e.g., other rotational component. In addition, rotational component **1602** also include implements **1510** on a surface of rotational com-

35

ponent **1602** that is configured to rotate substantially non-perpendicular to a rotational axis of rotary unit **1600**. Essentially any implement is optionally adapted for use with rotary unit **1600**, including the exemplary implements described herein. Rotary unit **1600** is typically included in a rotational mechanism, a device or the like. Exemplary rotational mechanisms that include rotary unit **1600** are described herein. In addition, representative devices that are optionally adapted to include rotary unit **1600** are also described herein.

In some embodiments, rotary unit **1600** also includes gear structure **1612**, which includes support component **1614** and first planetary gear components **1616** and second planetary gear components **1618** rotatably coupled to support component **1614**. As shown, first planetary gear components **1616** are configured to operably engage or mesh with first ring gear component **1604**, second planetary gear components **1618** are configured to operably engage or mesh with second ring gear component **1606**, and rotational component **1602** is configured to rotate relative to support component **1614**, which is substantially fixedly positioned (e.g., in an assembled rotational mechanism, device, etc.) when rotational component **1602** rotates relative to support component **1614**. As also shown, for example, in FIGS. **16 A** and **B**, respectively, first ring gear component **1604** at least partially defines first gear structure receiving area **1605** and second ring gear component **1606** at least partially defines second gear structure receiving area **1607**. First gear structure receiving area **1605** and second gear structure receiving area **1607** are configured to receive first portion **1622** and second portion **1624**, respectively, of support component **1614** of gear structure **1612**. First portion **1622** and second portion **1624** of support component **1614** of gear structure **1612** are described, e.g., further below.

FIG. **16G** schematically shows an exploded side view of gear structure **1612** according to one embodiment of the invention. As shown, threaded region **1620** of first portion **1622** of support component **1614** inserts into a threaded region receiving area (not within view in FIG. **16G**) of second portion **1624** of support component **1614** during assembly of gear structure **1612**. In addition, first planetary gear components **1616** are rotatably coupled to second portion **1624** of support component **1614** via pronged retaining elements **1626** and second planetary gear components **1618** are rotatably coupled to first portion **1622** of support component **1614** via pronged retaining elements **1628** during assembly of gear structure **1612**. As also shown, first portion **1622** and second portion **1624** of support component **1614** include friction reducing materials **1630** (shown as elevated or pointed surface features), e.g., to minimize friction when rotational component **1602** rotates relative to support component **1614** during operation of assembled rotary unit **1600**. To further illustrate, FIG. **16M** schematically shows an exploded view of rotary unit **1600** with first portion **1622** and second portion **1624** of support component **1614** of gear structure **1612** prior to assembly with rotational component **1602**.

To further illustrate, FIG. **16K** schematically illustrates gear structure **1612** prior to assembly with another gear structure **1612** from a side view according to one embodiment of the invention. As shown, during assembly, threaded region **1632** of one support component **1614** is inserted into threaded region receiving area **1634** of another support component **1614** such that the assembled support components **1614** are substantially fixedly positioned relative to one another, e.g., when rotational components **1602** of rotary units **1600** rotate relative to support components **1614**. Essentially any attachment technique is optionally utilized to attach support components **1614** of gear structures **1612** to one another or first

36

portion **1622** and second portion **1624** of support component **1614** to one another. Some exemplary techniques include, for example, bonding, welding, adhering, or the like. In some embodiments, multiple support components **1614** are fabricated as single integral part (e.g., as a molded part or the like).

FIGS. **42 A-G** schematically illustrate rotary units or components thereof from various views according to one exemplary embodiment of the invention. As shown, rotary unit **4200** or rotary unit **4202** each include rotational component **4204**, which includes gear component **4206** (e.g., a ring gear component) and surface **4208** that includes implements **4210**. Rotational component **4204** is configured to rotate around rotational axis **4212**. Surface **4208**, which includes implements **4210** is configured to rotate substantially non-perpendicular to rotational axis **4212**. In some of these embodiments, surface **4208** is configured to rotate substantially parallel to rotational axis **4212** of rotational component **4204**. Rotary unit **4200** includes first gear component **4214** and third gear component **4216**. First gear component **4214** operably engages (e.g., meshes with) gear component **4206** such that when first gear component **4214** rotates in a first direction, rotational component **4204** rotates in the first direction. Rotary unit **4202** includes second gear component **4218** operably engages (e.g., meshes with) gear component **4206** of rotational component **4204**. Second gear component **4218** operably engages (e.g., meshes with) third gear component **4216** when rotational component **4204** of rotary unit **4200** is disposed proximal to (e.g., operably engages) rotational component **4204** of rotary unit **4202** such that when first gear component **4214** rotates in the first direction, the rotational component **4204** of rotary unit **4200** rotates in the first direction and second gear component **4218** and rotational component **4204** of rotary unit **4202** rotate in a second direction.

Rotational component **4204** also includes alignment component **4220** and alignment component receiving area **4222**. Alignment component **4220** and alignment component receiving area **4222** are configured to align rotational component **4204** relative to other rotational components when the other rotational components are disposed proximal to rotational component **4202**. For example, alignment component **4220** of rotational component **4204** is configured to be received by an alignment component receiving area of another rotational component, while alignment component receiving area **4222** of rotational component **4204** is configured to receive an alignment component of another rotational component.

The drive mechanism components or portions thereof of the rotary units of the invention include various embodiments. Rotary unit **4200**, for example, includes drive mechanism component or portion thereof **4224** (e.g., shown as a shaft component), which operably engages first gear component **4214** and at least one other gear component (i.e., third gear component **4216** in this embodiment). Drive mechanism component or portion thereof **4224** is configured to effect rotation of first gear component **4214** and third gear component **4216**. To further illustrate, rotary unit **4202** includes drive mechanism component or portion thereof **4226** (e.g., shown as a shaft component), which operably engages second gear component **4218**. Drive mechanism components or portions thereof, including drive mechanism component receiving areas are described further herein.

III. Exemplary Rotary Mechanisms

In certain embodiments, the invention provides rotary or rotational mechanisms that include two or more rotational components or rotary units (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, 11,

12, 13, 14, 15, or more rotational components or rotary units). Rotary mechanisms also typically include at least one counter-rotational mechanism operably coupled to one or more of the rotational components. The counter-rotational mechanism is generally configured to effect substantially simultaneous counter-rotation of the rotational components relative to one another when movement of at least a portion of the counter-rotational mechanism is effected. Rotary mechanisms also typically include drive mechanisms operably coupled to the counter-rotational mechanism and/or rotational components. Drive mechanisms are typically configured to effect movement of at least the portion of the counter-rotational mechanisms such that the rotational components substantially simultaneously counter-rotate relative to one another. In some embodiments, for example, multiple rotary units are included as components (e.g., rotational components and counter-rotational mechanisms, etc.) of rotary mechanisms.

In some embodiments, rotary units are operably coupled to one another via one or more shafts. To illustrate one embodiment, FIG. 17A schematically depicts rotary units 100 and drive mechanism component 1702 (shown as a shaft) prior to assembly. As shown, gear component 1704 is fixedly coupled to shaft 1702 and is configured to operably engage third gear components 114 (not within view in FIGS. 17A and B) of a rotary unit 100 in assembled rotary mechanism 1700. During assembly, shaft 1702 is inserted through drive mechanism component receiving areas 122 (shown as holes, e.g., in FIG. 1A) of rotary units 100 to operably couple rotary units 100 to one another. FIG. 17B schematically illustrates rotary units 100 and shaft 1702 following assembly. Suitable shafts include a variety of cross-sectional shapes (e.g., circular, oval, triangular, square, rectangular, polygonal, etc.). In some embodiments, a given shaft includes multiple cross-sectional shapes. In some of these embodiments, individual rotary units include drive mechanism component receiving areas (e.g., holes, apertures, etc.) that correspond to those different cross-sectional shapes. In some embodiments, for example, one member of a pair of neighboring rotary units includes a square hole that fits on a square cross-section of a shaft, while the other member of the pair includes a circular hole that fits on a circular cross-section of the shaft. In these embodiments, the rotary unit with the square hole typically rotates in a substantially fixed position relative to the shaft, whereas the rotary unit with the circular hole typically rotates substantially free or independent relative to the shaft.

To further illustrate, FIGS. 18A-C schematically show rotary mechanism 1800 assembled from pairs of rotary units 700 and 800, which are both described further herein. More specifically, FIG. 18A schematically shows an individual pair of rotary units 700 and 800 prior to assembly of rotary mechanism 1800 from side views. FIG. 18B schematically shows partially assembled rotary mechanism 1800 with the rotary units of FIG. 18A from side views. FIG. 18C schematically illustrates rotary mechanism 1800 that includes multiple pairs of rotary units 700 and 800.

In some embodiments, rotary units are operably coupled to one another via one or more shafts. To illustrate one embodiment, FIG. 19A schematically depicts rotary units 900, drive mechanism component 1902 (shown as a shaft), and cap component 1903 prior to assembly. As shown, gear component 1904 is fixedly coupled to shaft 1902 and is configured to operably engage or mesh with gear components 914 of a rotary unit 900 in assembled rotary mechanism 1900. During assembly, shaft 1902 is inserted through drive mechanism component receiving areas 925 (shown as a hole, e.g., in FIG. 9A) of rotary units 900 to operably couple rotary units 900 to

one another. Shaft 1902 operably connects with cap component 1903 in assembled rotary mechanism 1900, e.g., to hold rotary units 900 in position relative to one another. FIG. 19B schematically illustrates rotary units 900, shaft 1902, and cap component 1903 following assembly of rotary mechanism 1900. The directional arrows in FIG. 19B schematically depict that neighboring pairs of rotary units 900 in rotary mechanism 1900 are configured to counter-rotate relative to one another. FIG. 19C schematically shows a portion of a rotary mechanism that includes rotary units 900 with implementations 918.

FIGS. 20A-O schematically show a rotary mechanism or components thereof according to exemplary embodiments of the invention. As shown, rotary mechanism 2000 includes four rotary units that each include rotational component 1302 and gear component 1304. Rotary mechanism 2000 also includes a drive mechanism that includes shafts 2002 and motors 2004. Motors 2004 are configured to effect rotation of shafts 2002. As shown, the drive mechanism is configured to effect rotation of gear components 1304 such that rotational components 1302 of neighboring or adjacent pairs of rotary units rotate in opposite directions. See, e.g., the directional arrows in FIG. 20H, which schematically depict the counter-rotation of neighboring pairs of rotational components 1302. As shown, one shaft 2002 is operably connected to a first set of two non-neighboring gear components 1304, while the other shaft 2002 is operably connected to a second set of two non-neighboring gear components 1304 that is different from the first set of two non-neighboring of gear components 1304. The two shafts 2002 are configured to rotate in opposite directions. See, e.g., the directional arrows associated with shafts 2002 in FIGS. 20H and I. As also shown, surfaces 1305 of rotational components 1302 are configured to rotate substantially non-perpendicular to a rotational axis of rotational components 1302.

Any suitable drive mechanism is optionally utilized with these rotary mechanisms. For example, FIG. 20L schematically depicts a portion of a drive mechanism from a side view. As shown, the drive mechanism includes motor 2004 (depicted as a dual shaft motor) that is configured to effect rotation of shafts 2002 in opposite directions via meshing pairs of gear components 2006. To further illustrate, FIGS. 20M-O schematically depict portions of a drive mechanism. As shown, motor 2004 is configured to effect rotation of shafts 2002 in opposite directions via a gear train that includes gear components 2008.

In addition, rotary mechanism 2000 also includes positioning component 2010 (shown as a frame structure) that is configured to position rotary units relative to one another. As shown, shafts 2002 are positioned relative to positioning component 2010 via mount brackets 2012, which permit rotation of shafts 2002. As also shown, positioning component 2010 also includes a plurality of friction reducing materials 2014 (shown as roller balls) disposed on a surface of positioning component 2010 to reduce friction as rotational components 1302 rotates relative to positioning component 2010. In the embodiments in which friction reducing materials are utilized, essentially any friction reducing material is optionally adapted for use with the rotary mechanisms of the invention. Other exemplary embodiments include, for example, coatings (e.g., TEFLON®, etc.), lubricants, surface features, and/or the like. FIG. 20G schematically depicts positioning component 2016 according to another exemplary embodiment.

FIGS. 21A-E schematically show rotary mechanisms or components thereof according to exemplary embodiments of the invention. As shown, rotary mechanism 2100 includes

drive mechanism component **2102**, which includes ring gear component **2104** and a gear structure. The gear structure includes support component **2106** and planetary gear component **2108** rotatably coupled to support component **2106**. Planetary gear component **2108** is configured to operably engage ring gear component **2104** of drive mechanism component **2102** and gear component **1410** of rotary unit **1400**. Drive mechanism component **2102** also includes motor **2110**, which is configured to effect rotation of ring gear component **2104** via shaft **2112**. Shaft **2112** is fixedly connected to ring gear component **2104**. When ring gear component **2104** rotates, it effects the counter-rotation of neighboring pairs of rotary units **1400** relative to one another. See, e.g., the directional arrows associated with FIGS. **21B** and **C**, which schematically depict the counter-rotation of neighboring pairs of rotary units **1400**. As also shown, in assembled rotary mechanism **2100**, support component **2106** is operably connected to support components **1417** of rotary units **1400** such that support component **2106** and support components **1417** are substantially fixedly positioned relative to one another when ring gear component **2104** effects the counter-rotation of neighboring pairs of rotary units **1400** relative to one another. Gear structures that include support components **1417** are described further herein. To further illustrate, FIG. **21D** schematically depicts rotary mechanism **2114**, which includes rotary units **1400** with implements **1418**. In addition, FIG. **21E** schematically illustrates rotary mechanism **2116**, which includes rotary units **1400** with implements **1418** and dual shaft motor **2118**.

The gear structures of the invention include various embodiments. To illustrate, FIG. **22A** schematically illustrates gear structure **1415** prior to assembly with another gear structure **1415** from a side view according to one embodiment of the invention. As shown, gear structure **1415** includes support component **1417** and gear components **1414** (e.g., planetary gear components or the like), which are rotatably coupled to support component **1417**. Gear components **1414** are configured to operably engage or mesh with one or more other gear components when gear components **1414** are disposed proximal to the other gear components. During assembly, threaded region **1429** of one support component **1417** is inserted into threaded region receiving area **1427** of another support component **1417** such that the assembled support components **1417** are substantially fixedly positioned relative to one another when rotational components **1402** of rotary units **1400** rotate relative to support components **1417** and to one another. Essentially any attachment technique is optionally utilized to attach support components **1417** to one another. Some exemplary techniques include, for example, bonding, welding, adhering, or the like. In some embodiments, multiple support components **1417** are fabricated as single integral part (e.g., as a molded part or the like). FIG. **22B** schematically shows an assembly of four gear structure **1415** from a side view. FIG. **22C** schematically depicts the gear structure assembly of FIG. **22B** from a rear side view, while FIG. **22D** schematically depicts the gear structure assembly of FIG. **22B** from a front side view.

To further illustrate, FIG. **22E** schematically shows rotary mechanism **2200** that includes the gear structure assembly of FIG. **22B** from a sectional view according to one embodiment of the invention. As shown, rotary mechanism **2200** includes four rotary units **1400**. Counter-rotation of neighboring rotational components **1402** in rotary mechanism **2200** is effected by drive mechanism component **2202**, which includes shaft component **2204** and gear component **2206**. FIG. **22F** schematically shows rotary mechanism **2200** from a side view. Rotational components **1402** of rotary units **1400** of rotation

mechanism **2200** are configured to rotate relative to support components **1417**, which support components **1417** are substantially fixedly positioned when rotational components **1402** rotates relative to support components **1417**. Gear components **1414** are configured to rotate relative to rotational components **1402**.

FIGS. **23A-T** schematically depict a rotational mechanism or components thereof according to one embodiment of the invention. To illustrate, FIGS. **23A** and **C**, for example, schematically depicts a portion of rotational mechanism **2300** from an exploded side and exploded side sectional views, respectively. During assembly of rotational mechanism **2300**, support component **1614** of one rotary unit **1600** is inserted through hole **1508** of rotary unit **1500** and threaded region **1632** of that support component **1614** is received and retained in threaded region receiving area of another rotary unit **1600**.

FIGS. **23E-P** schematically show a portion of a drive mechanism component that is utilized to effect counter-rotation of neighboring pairs of rotary unit **1500** and rotary unit **1600** of rotational mechanism **2300**. As shown, the portion of the drive mechanism component includes rotational component **2302**, which includes ring gear component **2304**, hole **2306**, and implements **2308**. The portion of the drive mechanism component also includes gear structure **2310**, which includes support structure **2312** and planetary gear components **2314** rotatably coupled to support structure **2312**. Support structure **2312** also includes friction reducing materials **2316** (shown as elevated or pointed surface features) to, e.g., reduce friction between support structure **2312** and rotational component **2302** when rotational component **2302** rotates relative to support structure **2312**. Support structure **2312** also includes threaded region **2318**, which is received by a corresponding threaded region receiving area of fastener **2320** (e.g., a nut or the like) through hole **2306** to hold gear structure **2310** in position relative rotational component **2302**, yet permit rotational component **2302** to rotate relative to support structure **2312** and planetary gear components **2314**. In addition, support structure **2312** also includes threaded region receiving area **2322**, which is configured to receiving thread region **1632** of a rotary unit **1600**, e.g., in assembled rotational mechanism **2300**.

As also shown, a shaft **2324** is also fixedly connected to rotational component **2302**. Although not shown, a motor or the like is typically operably connected to shaft **2324**, which effects the rotation of shaft **2324** and the counter-rotation of neighboring pairs of rotary unit **1500** and rotary unit **1600** of rotational mechanism **2300** (e.g., as schematically depicted by the directional arrows shown, e.g., in FIG. **23S**) during operation. In addition, a rotary unit **1600** also operably connects to support component **2326** via threaded region receiving area **1634** of support structure **1614**, e.g., such that support structures **1614** of rotary units **1600** and support structure **2312** of gear structure **2310** are substantially fixedly positioned when rotary units **1500**, rotary units **1600**, and rotational component **2302** rotate relative to one another in rotational mechanism **2300**. Essentially any support component is optionally used. In some embodiments, support components are included in or as part of devices, apparatus, or other applications of the rotational mechanisms of the invention. Exemplary support components and applications are described herein.

FIGS. **43A-I** schematically illustrate a rotary mechanism or components thereof from various views according to one exemplary embodiment of the invention. As shown, rotary mechanism **4300** includes rotational components **4204**, which include gear components **4206** (e.g., ring gear components). Rotary mechanism **4300** also includes counter-rotation

41

tional mechanism **4313** that includes first gear components **4214** that operably engage (e.g., mesh with) a ring gear component **4206** of a first rotational component **4204** of a neighboring pair of rotational components. Counter-rotational mechanism **4313** also includes second gear components **4218** that operably engage (e.g., mesh with) a ring gear component **4206** of a second rotational component **4204** of a neighboring pair of rotational components. Counter-rotational mechanism **4313** also includes third gear components **4216** that operably engage (e.g., mesh with) second gear components **4218** such that when first gear components **4214** rotate in a first direction, first rotational components **4204** of neighboring pairs of rotational components rotate in the first direction and second gear components **4218** and second rotational components **4204** of neighboring pairs of rotational components rotate in a second direction (e.g., substantially opposite the first direction).

Rotational components **4204** include alignment components **4220** and alignment component receiving areas **4222** that are configured to align rotational components **4204** relative to one another, e.g., when rotational components **4204** rotate. As shown, an alignment component receiving area **4222** of a given rotational component **4204** is configured to receive at least a portion of an alignment component **4220** of another rotational component **4204**. In this exemplary embodiment, alignment components **4220** are shown as circular ridge structures. Other alignment components or mechanisms are also optionally used to align rotational components relative to one another in the rotary mechanisms of the invention. In some embodiments, friction reducing materials are disposed between neighboring pairs of rotational components in a rotary mechanism to reduce friction between the rotational components when the rotational components rotate relative to one another. In some embodiments, for example, one or more lubricants are disposed between at least one neighboring pair of rotational components **4204** before and/or after the alignment component **4220** of one rotational component **4204** is inserted into the alignment component receiving area **4222** of another rotational component **4204**. Other exemplary friction reducing materials that are optionally used or adapted for use with the rotary mechanisms of the invention are described herein or otherwise known to those of skill in the art.

Rotary mechanism **4300** also includes drive mechanism components or portions thereof **4224** and **4226** (e.g., shown as shaft components in this exemplary embodiment). As shown, shaft component **4224** operably engages first gear components **4214** and third gear components **4216**, while shaft component **4226** operably engages second gear components **4218**. As also shown, rotary mechanism **4300** also includes drive mechanism components or portions thereof **4302** (e.g., shown as motor in this exemplary embodiment) operably connected to shaft component **4224**. Motor **4302** is configured to effect rotation of shaft component **4224** and thereby first gear components **4214** and third gear components **4216** as well as shaft component **4226** and second gear components **4218** such that when first gear components **4214** rotate in a first direction, first rotational components **4204** of neighboring pairs of rotational components rotate in the first direction and second gear components **4218** and second rotational components **4204** of neighboring pairs of rotational components rotate in a second direction (e.g., substantially opposite the first direction). Rotary mechanism **4300** is typically operably incorporated into, or otherwise operably associated with, a device, vehicle, or the like. Exemplary devices,

42

vehicles, or other applications that are optionally used or adapted for use with rotary mechanism **4300** or the like are, e.g., described further herein.

The rotary mechanisms of the invention or components thereof are fabricated or assembled using various techniques. In some embodiments, rotary mechanisms are assembled using rotational components that include multiple portions. As shown in FIGS. **44 A-C**, for example, a rotary mechanism is optionally assembled using rotational components **4400**, which each include rotational component portion **4402** and rotational component portion **4404**. Rotational component portions **4402** and rotational component portions **4404** include portions of the ring gear components, alignment components, and alignment component receiving areas described herein, e.g., with respect to rotational components **4204**. Rotational component portions **4402** also include alignment features **4406** and rotational component portions **4404** also include corresponding alignment feature receiving areas (not within view) that are configured to receive alignment features **4406**. As shown, during assembly, rotational component portions **4402** and rotational component portions **4404** are joined (e.g., adhered, bonded, welded, etc.) with one another and positioned in operable engagement with first gear components **4214** and second gear components **4218** to form rotary mechanisms.

In certain embodiments, rotary mechanisms are assembled using shaft components that include multiple portions. FIGS. **45 A and B**, **46 A and B**, **47 A and B**, and **48** show aspects of one of these exemplary embodiments. As shown, shaft component portion **4500** includes drive mechanism component receiving area **4700** and shaft component portion **4502** includes notched portion **4702** that is configured to be received by drive mechanism component receiving area **4700** of shaft component portion **4500**. Shaft component portion **4500** and shaft component portion **4502** are each operably connected to a first gear component **4214**. In addition, shaft component portion **4504** includes drive mechanism component receiving area **4700** and shaft component portion **4506** includes notched portion **4702** that is configured to be received by drive mechanism component receiving area **4700** of shaft component portion **4504**. Shaft component portion **4504** and shaft component portion **4506** are each operably connected to a second gear component **4218**. As shown, for example, in FIG. **48** rotational components **4204** are positioned relative to first gear components **4214** operably connected to shaft component portion **4500** or shaft component portion **4502** or second gear components **4218** operably connected to shaft component portion **4504** or shaft component portion **4506** and corresponding drive mechanism component receiving areas **4700** and notched portions **4702** are joined together during the assembly of a rotary mechanism in this exemplary embodiment. In some embodiments, multiple shaft portions and multiple rotational component portions are used together in the assembly of rotary mechanisms. Other exemplary rotary mechanism or component fabrication and assembly techniques are described herein.

As also shown, rotational components **4204** of rotary mechanism **4300** also include implements **4210**. Other exemplary implements that are optionally used or adapted for use with rotational components **4204** are described further herein. In some embodiments, for example, implements are rotatably coupled to rotation components. In some of these embodiments, implements are configured to operably engage one or more gear components of one or more other rotational components. Rotatably coupled implements are described further herein, for example, with respect to FIGS. **6A-E**, **27A-D**, **28 A and B**, and **29**.

FIGS. 51 A-F schematically show a rotary mechanism or components thereof from various views according to one exemplary embodiment of the invention. As shown, rotary mechanism 5100 includes rotary units that include rotational components 4204. Rotational components 4204 include gear components 4206 (e.g., ring gear components). Additional details about rotational components (e.g., rotational components 4204) are described further herein. The rotary units also include second gear components 4218, which are configured to operably engage gear components 4206 of rotational components 4204. Rotary mechanism 5100 also includes a drive mechanism component or portion thereof that operably engages second gear components 4218. The drive mechanism component or portion thereof is configured to effect rotation of second gear components 4218 such that rotational component 4204 of one rotary unit of a neighboring pair of rotary units rotates in a first direction and rotational component 4204 of the other rotary unit of the neighboring pair of rotary units rotates in a second direction. As shown, the drive mechanism component or portion thereof includes shaft component 5102 and shaft component 5104. Shaft component 5102 operably engages second gear components 4218 of one rotary unit of each neighboring pair of rotary units, while shaft component 5104 operably engages second gear components 4218 of the other rotary unit of each neighboring pair of rotary units. Shaft component 5102 and shaft component 5104 are also operably connected to drive gear components 5106 and 5108, respectively. In assembled rotary mechanism 5100, drive gear components 5106 and 5108 mesh with one another. As shown, shaft component 5102 is also operably connected to motor 5110. Motor 5110 is configured to effect rotation of shaft component 5102 and thereby second gear components 4218 and corresponding rotational components 4204 of one rotary unit of each neighboring pair of rotary units in a first direction and second gear components 4218 and corresponding rotational components 4204 of the other rotary unit of each neighboring pair of rotary units via drive gear components 5106 and 5108 and shaft component 5104 in a second direction. In some embodiments, rotary mechanisms also include drive mechanism positioning components that are configured to position drive mechanism components or portions thereof relative to one another. To illustrate, rotary mechanism 5100 includes drive mechanism positioning component 5112, which includes holes 5114. Shaft component 5102 and shaft component 5104 are configured to fit and rotate within holes 5114 such that shaft component 5102 and shaft component 5104 are positioned relative to one another at least during rotation. Rotary mechanism 5100 is typically operably incorporated into, or otherwise operably associated with, a device, vehicle, or the like. Exemplary devices, vehicles, or other applications that are optionally used or adapted for use with rotary mechanism 5100 or the like are, e.g., described further herein.

IV. Exemplary Applications

FIGS. 24 A and B schematically illustrate a rotor tiller or rototiller that includes a rotary mechanism according to one embodiment of the invention. As shown, rotor tiller 2400 includes rotary mechanism 2462 that is operably connected to motor 2404 via shaft 2474. As also shown, rotor tiller 2400 also includes wheels 2402 and handle 2406 coupled to a support structure.

To further illustrate exemplary embodiments of the invention, FIG. 25A schematically shows vehicle 2500 from a side elevational view. As shown, vehicle 2500 includes two rotary mechanisms 2502 and grading blade 2503, which can each be

independently raised and lowered. Rotary mechanisms can include various embodiments, including various types of implements (e.g., as described herein or the like). As also shown, vehicle 2500 also includes wheels 2504, driver's compartment 2506, and engine compartment 2508. Vehicle 2500 can be adapted for a wide variety of uses in, e.g., agricultural, construction, military, or other applications. In some embodiments, for example, vehicle 2500 is used to till, grade, and/or otherwise move soil. As another exemplary illustration, FIG. 25B schematically shows vehicle 2501 from a side elevational view. As shown, vehicle 2501 includes rotary mechanism 2510, which can be raised and lowered. As also shown, vehicle 2501 also includes wheels 2504, driver's compartment 2506, and engine compartment 2508. Vehicle 2501 can be adapted for a wide variety of uses. In some embodiments, for example, vehicle 2501 is used to till, grade, and/or otherwise move soil.

In other representative embodiments, the invention provides hair cutting devices, e.g., for cutting facial hair, leg hair, or hair on other body parts. To illustrate, FIGS. 26 A-G illustrate various aspects of a hair cutting device according to one embodiment of the invention. As shown, hair cutting device 2600 includes housing 2602, which comprises surfaces that define cavity 2604 disposed at least partially within housing 2602. Housing 2602 also includes opening 2606 that communicates with cavity 2604. Rotary mechanism 2608 (e.g., similar to the rotary mechanism described with respect to FIG. 18C) is at least partially disposed within cavity 2604. Rotary mechanism 2608 includes multiple rotational components 2610 and 2612 (such as the rotational components described with respect to FIGS. 7A-C and 8A-C, etc.) that are configured to substantially coaxially rotate (e.g., coaxially counter-rotate) relative to one another. Rotational components 2610 and 2612 also include cutting implements 2614 (e.g., razor blades or other sharp edges) that are configured to cut hair via opening 2606 when the multiple rotational components 2610 and 2612 substantially coaxially rotate relative to one another and cutting implements 2614 (see, e.g., implements 716 and 818 or the like) contact the hair (see, e.g., FIG. 26F). Rotary mechanism 2608 also includes at least one counter-rotational mechanism, as described herein (see, e.g., the multiple assembled rotational mechanisms schematically depicted in, e.g., FIGS. 18A-C or the like), operably coupled to the multiple rotational components 2610 and 2612. The counter-rotational mechanism is configured to effect substantially simultaneous counter-rotation of the multiple rotational components 2610 and 2612 relative to one another when movement of at least a portion of the counter-rotational mechanism is effected. That is, rotational component 2610 is configured to rotate in a direction that is opposite the direction of rotation of rotational component 2612. In some embodiments, the rotational components are configured to coaxially counter-oscillate relative to one another about an axis of rotation of the rotary mechanism. In some of these embodiments, cutting implements include dual-side cutting edges, e.g., to cutting hair in both directions of the oscillation.

As also shown, hair cutting device 2600 also includes a drive mechanism operably coupled to the counter-rotational mechanism and rotational components. In the embodiment shown, for example, in FIGS. 26A and 26C, the drive mechanism includes motor 2616 (e.g., a stepper motor, a servo motor, etc.), which is configured to effect movement of the counter-rotational mechanism via shaft 2618 such that the multiple rotational components 2610 and 2612 substantially simultaneously counter-rotate relative to one another. As also shown, switch 2617 (e.g., on/off switch, a variable speed control switch, and/or the like) is operably connected to

motor **2616**. Although not shown, hair cutting device **2608** also typically includes a power source (e.g., a power cord that plugs into a wall socket, a battery (rechargeable or not), a photovoltaic cell, etc.) operably connected to motor **2616**.

Hair cutting device **2600** also includes removable structure **2620** (e.g., a shaving foil structure or the like) disposed in opening **2606**. Removable structure **2620** comprises holes **2622** via which hair is cut when the multiple rotational components **2610** and **2612** substantially coaxially counter-rotate relative to one another and cutting implements **2614** contact the hair. Hair cutting devices also typically include support structures that are structured to support at least a portion of the rotational components, the counter-rotational mechanism, and/or the drive mechanism within the device housings. As shown in FIG. **26F**, for example, hair cutting device **2600** is dimensioned to be hand-held (i.e., person **2621** is holding hair cutting device **2600** in his hand). As shown, e.g., FIG. **26G** housing **2602** of hair cutting device **2600** comprises at least one substantially circular cross-section.

FIGS. **27 A-D** schematically illustrate an exemplary tooth brushing device or components thereof according to one embodiment of the invention. As shown, tooth brushing device **2700** includes rotary mechanism **2702**, which includes a plurality of rotary units **600**, as described above. Tooth brushing device **2700** also includes toothbrush head component **2704** and handle component **2706**. Toothbrush head component **2704** includes rotary mechanism housing **2708**, which partially exposes a portion of the bristles of rotary mechanism **2702** through an opening in rotary mechanism housing **2708** during operation. Toothbrush head gear components **2710** and drive shaft **2712** also extend from a portion of rotary mechanism housing **2708**. Drive shaft **2712** is received through drive mechanism receiving areas of rotational components **602** of rotary units **600** of rotary mechanism **2702**. Toothbrush head gear components **2710** operably engage gear components **604** and **624** of a rotary unit **600** to effect counter rotation of neighboring rotational components **602** and implements **622** of rotary mechanism **2702**. Rotary mechanism cap **2714** attaches to drive shaft **2712** to retain rotary mechanism positioned relative to toothbrush head gear components **2710**. Handle component **2706** houses a motor (not within view) that operably connects to toothbrush head gear components **2710** and drive shaft **2712**. A power source, such as a rechargeable battery or the like is also housed in handle component **2706** is some embodiments. In certain embodiments, the motor is optionally connected to other types of power sources, such as photovoltaic cells attached to handle component **2706**, external power sources, or the like. As also shown, handle component **2706** also include switch **2716**, which is used, e.g., to turn tooth brushing device **2700** on and off, regulate speeds or modes of rotary unit rotation, or the like.

FIGS. **28 A** and **B** schematically show an exemplary rotary mechanism or toothbrush head component that is optionally used, e.g., with handle component **2706** of tooth brushing device **2700**. As shown, rotary mechanism **2800** includes a plurality of rotary units **600** in which implements **2802** (raised elastomeric regions, e.g., for tooth polishing) have been substituted for implements **622** on several individual rotary units. FIG. **28B** schematically shows toothbrush head component **2804**, which includes rotary mechanism **2800**.

FIG. **29** schematically illustrates an exemplary cleaning device from a side view according to one embodiment of the invention. As shown, cleaning device **2900** includes a rotary mechanism that includes rotary units similar to rotary units **800**, which are described further herein. Exemplary uses of

cleaning device **3900** include cleaning outdoor cooking grills, dishes, and toilets, among many possible applications.

To further illustrate representative embodiments, rotary units and rotary mechanisms are optionally used or adapted for use in various types of engines and other propulsion devices or systems. For example, FIGS. **30 A-F** schematically illustrate a propulsion device or components thereof according to one embodiment of the invention. As shown, propulsion device **3000** includes two rotary mechanisms **3002** and propeller component **3004**. Rotary mechanisms **3002** include a plurality of rotary units **300**, as described herein. Rotary units **300** are operably coupled to one another via shaft **3006**, which includes gear component **3008**. Shaft **3006** operably connects to motor **3010** and rotary mechanism cap **3012**. Gear component **3008** operably engages third gear components **312** of gear structure **310** of a rotary unit **300** such that when motor **3010** effects the rotation of gear component **3008**, gear component **3008** effects the counter rotation of neighboring pairs of rotary units **300**. Gear components **324** of rotary units **300** operably engage corresponding gear components of propeller units **3014** (e.g., rotational units or the like) to effect the counter rotation of neighboring pairs of propeller units **3014** of propeller component **3004**, and thereby propulsion. Rotary mechanism cap **3012** aligns and maintains the position of rotary units **300** relative to one another. Although two rotary mechanisms **3002** are depicted in this propulsion device embodiment, fewer or more than two rotary mechanisms are optionally used.

FIGS. **32 A-D** schematically illustrate a propulsion device or components thereof according to one embodiment of the invention. As shown, propulsion device **3200** includes two rotary mechanisms **3202** and propeller component **3004**. Rotary mechanisms **3202** include a plurality of rotational components **3204**. Rotational components **3204** are fixedly coupled to one another via shaft **3206**. Shaft **3206** operably connects to motor **3010** and rotary mechanism cap **3012**. As shown, one shaft **3206** is fixedly coupled to a first set of four non-neighboring gear components **3204**, while the other shaft **3206** is fixedly coupled to a second set of four non-neighboring gear components **3204** that is different from the first set of four non-neighboring of gear components **3204**. The two shafts **3206** are configured to rotate in opposite directions. See, e.g., the directional arrows associated with the two rotary mechanisms **3202** in FIG. **32B**. As shown, in an assembled propulsion device **3200**, gear components **3204** of the first and second sets of four non-neighboring of gear components **3204** mesh with corresponding gear components of different propeller units **3014** (e.g., rotational units or the like) of propeller component **3004** such that when the first and second sets of four non-neighboring of gear components **3204** rotate in opposite directions to one another, neighboring pairs of propeller units **3014** of propeller component **3004** counter-rotate relative to one another, and thereby effect propulsion.

Propeller component **3004** of propulsion device **3000** and **3200** includes a plurality of propeller units **3014** (e.g., rotational units or the like), which in this embodiment each include a plurality of propellers **3016**. Many different types of propellers are optionally used or adapted for use in the engines or propulsion devices of the invention. In some embodiments, for example, individual propeller components **3004** may have propellers **3016** that differ in size from the propellers of other propeller components in a given propulsion device **3000** or propulsion device **3200**. Propeller units **3014** are operably coupled together in propeller component **3004** via propeller component shaft **3018** and propeller component cap **3020**. As also shown, certain propeller units **3014** include rotational alignment components **3022**, which are

positioned and rotate in corresponding rotational positioning components **3107** of propulsion component housing **3100** (e.g., a positioning component or the like), e.g., to prevent propeller units **3014** from contacting propulsion component housing **3100** during operation. See, e.g., FIGS. **31 D** and **E**.

The engine and propulsion devices have many different uses. For example, they are optionally used or adapted for use with watercraft (e.g., boats, submarines, surfboards, personal watercraft, diving or scuba propulsion aides, and the like) or aircraft. To illustrate, FIGS. **33 A** and **B** schematically depict boat **3300**, which includes several housed propulsion devices **3302**. To further illustrate, FIGS. **34 A** and **B** schematically depict aircraft **3400**, which includes housed propulsion devices **3402**.

FIG. **35A** schematically shows cleaning device **3500** that includes a rotary mechanism from a sectional view according to one embodiment of the invention. FIG. **35B** schematically shows cleaning device **3500** from a side view. As shown, the rotary mechanism of cleaning device **3500** includes rotary units **900**, which each include implements **918**. Rotary units **900** are aligned relative to one another and rotate around shaft **3502**. The rotary mechanism is positioned relative to housing **3504** via mounting components **3506**. As also shown, cleaning device **3500** also includes motor **3508**, which effects the counter-rotation of rotary units **900** in the rotary mechanism via drive shaft **3510** and meshed gear components **3512** and **3514**. Cleaning device **3500** also includes power source **3516** (e.g., a battery or the like), which is operably connected to motor **3508** and switch **3518** in a handle portion of housing **3504**. Cleaning device **3500** is optionally adapted for a variety of uses including, for example, cleaning dishes, cleaning countertops, cleaning floors, cleaning barbecue grills, cleaning ovens, cleaning toilets, buffing automobiles or other vehicles, and the like.

FIGS. **36A-G** schematically depict a cleaning device or components thereof. As shown, cleaning device **3600** includes rotary mechanism **3602**. Rotary mechanism **3602** includes rotary units **900**, which each include implements **918**. Rotary units **900** are aligned relative to one another and rotate around shafts **3604**. Rotary mechanism **3602** is positioned relative to housing **3606** of head component **3607** via mounting components **3608**. As also shown, cleaning device **3600** also includes motor **3610**, which effects the counter-rotation of rotary units **900** in rotary mechanism **3602** via drive shaft **3612** and meshed gear components **3614** and **3616**. Although not within view, cleaning device **3600** also includes a power source (e.g., a battery or the like) or is connectable with a power source (e.g., via a power cord or the like), which operably connects to motor **3610** and switch **3618**. As shown, switch **3618** is disposed on handle component **3620**, which operably connects to head component **3607**.

FIG. **37** schematically shows rotary mechanism **3700** from a top side view according to one embodiment of the invention. Rotary mechanism **3700** is optionally adapted for use in the cleaning devices and other applications of the invention. Rotary mechanism **3700** includes rotary units **900**, which each include implements **918**. Rotary units **900** are aligned relative to one another and rotate around shafts **3702**. As also shown, rotary mechanism **3700** also includes motor **3704**, which effects the counter-rotation of rotary units **900** in rotary mechanism **3700** via drive shaft **3706** and meshed gear components **3708**.

FIG. **38** schematically shows cleaning device **3800** that includes rotary mechanism **3602** from a side view according to one embodiment of the invention. As shown, cleaning device **3800** includes head component **3607** (as described above), which is operably connected to handle component

3802. As also shown, handle component **3802** includes switch **3804**, which is operably connected to motor **3610** (not within view). Switch **3804** is typically used to turn cleaning device **3800** on and off, varying a rate or mode of rotary unit rotation, and the like.

FIG. **39** schematically shows cleaning device **3900** that includes rotary mechanism **5502** from a side view according to one embodiment of the invention. As shown, cleaning device **3900** includes head component **3607** (as described above), which is operably connected to handle component **3902**. As also shown, handle component **3902** includes switch **3904**, which is operably connected to motor **3610** (not within view). Cleaning device **3900** also includes suction component **3906**, which communicates with an internal cavity of head component **3607** that includes rotary mechanism **3602** and with waste container **3908**. Suction component **3906** includes a suction source (e.g., a vacuum source) and a conduit. The suction source is configured to generate suction force sufficient to convey waste from head component **3607** through the conduit to waste container **3908**. Switch **3904** is also operably connected to suction component **3906**. Switch **3904** is typically used to turn cleaning device **3900** on and off (rotary unit rotation and/or suction), varying a rate or mode of rotary unit rotation and/or suction component suction, and the like.

FIG. **40A** schematically shows cleaning device **4000** that includes rotary mechanism **3602** and removable fluid containers **4002** (e.g., a fluid source or the like) and **4004** (e.g., a fluid waste container or the like) prior to assembly from a side view according to one embodiment of the invention. FIG. **40B** schematically shows cleaning device **4000** with fluid containers **4002** and **4004** positioned relative to handle **4006** on support components **4003** and **4005**, respectively, from a side view. As shown, cleaning device **4000** includes head component **3607** (as described above), which is operably connected to handle component **4006**. As also shown, handle component **4006** includes switch **4008**, which is operably connected to motor **3610** (not within view).

In some embodiments, cleaning devices or implements include fluid handling mechanisms that can be used, for example, to distribute fluid (e.g., a cleaning fluid, etc.) to a surface to be cleaned or the like. To illustrate one exemplary embodiment, cleaning device **4000** includes a fluid handling mechanism that comprises a fluid source (container **4002**) and fluid outlet (nozzle **4010**) (shown disposed proximal to a surface of head component **3607**). The fluid handling mechanism is configured to convey fluid from container **4002** to nozzle **4010**, which communicate via fluid conduit **4012**. The fluid handling mechanism of cleaning device **4000** also includes pumping mechanism **4014** (e.g., a rotary lobe pump, a rotary gear pump, a screw pump, a gear pump, a peristaltic pump, or the like) that is configured to pump the fluid from container **4002** to nozzle **4010**. As also shown, the fluid handling mechanism also includes vaporization component **4016** (e.g., a steam vaporizer or the like) that is configured to vaporize the fluid at least proximal to nozzle **4010**. In the embodiment shown, container **4002** is removable from cleaning device **4000** such that container **4002** can be, e.g., refilled with a cleaning fluid, replaced with a new container when container **4002** is fabricated as a consumable component of cleaning device **4000**, etc. In some embodiments, containers are fabricated integral or otherwise fixedly attached to cleaning devices. Switch **4008** is also configured to effect operation of pumping mechanism **4014** and vaporization component **4016**.

Cleaning device **4000** also includes suction component **4018** (e.g., vacuum source or component, pumping mecha-

nism, and/or the like) that comprises inlet **4020** and outlet **4022**. As shown, suction component **4018** is disposed proximal to head component **3607**. Outlet **4022** communicates with container **4004** via conduit **4024**. Switch **4008** is also configured to effect operation of suction component **4018**.

During operation, cleaning fluid is conveyed from container **4002**, vaporized, and sprayed from nozzle **4010** to wet a surface to be cleaned. Rotary mechanism **3602** of head component **3607** scrubs the wetted surface and suction component **4018** conveys waste fluid from the wetted surface through inlet **4020** to container **4004**. Cleaning devices or implements, or components thereof, that optionally are adapted for use with the cleaning devices of the invention are also described in, e.g., U.S. Provisional Patent Application No. 61/317,746, entitled "CLEANING IMPLEMENTS, CLEANING MATERIAL COMPONENTS, AND RELATED METHODS", filed on Mar. 26, 2010, which is incorporated by reference in its entirety.

To further illustrate, FIGS. **41 A-Q** schematically show cleaning devices, cleaning material components, or components thereof from various views according to exemplary embodiments of the invention. As shown, cleaning device **4100** includes head component **4102** which includes cleaning material support component **4104** and cleaning surface component **4106**. Cleaning material support component **4104** includes cleaning material support component surfaces **4108** that at least partially define cleaning material receiving areas **4110** (shown as cleaning implement cartridge receiving areas). As also shown, cleaning material support components **4104** include openings **4112** that are structured such that cleaning material receiving areas **4110** communicate with cleaning surface component **4106**. As shown, cleaning material receiving areas **4110** are configured to receive cleaning material component **4114** (shown as a cleaning implement cartridge that includes a cleaning material roll) such that at least a portion of cleaning material component **4114** is movable to and/or from cleaning material receiving area **4110** to extend over at least a portion of cleaning surface component **4106**. In addition, cleaning device **4100** also includes retaining component **4120** (shown as a door structure) that operably engages cleaning material support component **4104** via slide component **4122** in this exemplary embodiment. As shown, head component **4102** also includes rotary mechanism **2116**.

Cleaning material component **4114** includes cleaning material support structures **4130** and cleaning material **4126** (shown as a rolled sheet of cleaning material). Cleaning material support structures **4130** (shown as substantially cylindrically-shaped housings) form cavities that are each structured to house and support cleaning material **4126** such that cleaning material **4126** is movable to and/or from cleaning material support structures **4130** via orifices **4132**. Orifices **4132** are configured to communicate with openings **4112**. Cleaning material support structures and corresponding cleaning material receiving areas are optionally formed to include various cross-sectional shapes, including, e.g., circles, ovals, squares, rectangles, regular n-sided polygons, irregular n-sided polygons, etc. As shown, cleaning material support structure **4130** is configured to be received in cleaning material receiving area **4110** of cleaning device **4100** and cleaning material **4126** is configured to extend over cleaning surface component **4106** of cleaning device **4100** via orifices **4132** and openings **4112**.

In some embodiments, cleaning material support structures and/or cleaning materials of cleaning material components include one or more alignment components that are configured to align cleaning materials relative to cleaning material support structures. To illustrate, cleaning material

support structures **4130** of cleaning material component **4114** includes rod **4134** that extends within cleaning material support structure **4130**. As shown, the alignment component (rod **4134**) of cleaning material support structure **4130** inserts into a corresponding central receiving area of the cleaning material roll (cleaning material **4126**) to align cleaning material **4126** relative to cleaning material support structures **4130**.

In certain embodiments, cleaning devices and/or cleaning material components operably connect, or are operably connectable, to conveyance mechanisms or components thereof to effect conveyance of cleaning materials, e.g., selected incremental distances. In cleaning device **4100**, for example, rod **4134** extends through cleaning material support structure **4130** and operably connects to conveyance mechanism component **4140** that is configured to operably engage gear components **4139**. In particular, projections **4137** of conveyance mechanism component **4140** are configured to be received by projection receiving areas **4135** of gear components **4139**. Gear components **4139** are configured to operably engage gear component **4141** of head component **4102** when cleaning material component **4114** is disposed in cleaning material receiving areas **4110**. As shown, gear component **4141** is operably connected to motor **4143** (e.g., a stepper motor, a servo motor, etc.) via shaft **4145**. Power source **4147** (shown as a battery, e.g., a disposable battery, a rechargeable battery, etc.) operably connects to motor **4143** to provide power to motor **4143**. Essentially any power source is optionally adapted for use with the cleaning devices of the invention. In some embodiments, for example, motors are operably connected to power cords that plug into power outlets. In other exemplary embodiments, photovoltaic cells are mounted cleaning devices to provide power to motors. Motor **4143** effects rotation of cleaning material roll (cleaning material **4126**) (via gear components **4139** and **4141**) selected distances such that cleaning material **4126** is positioned at selected positions relative to cleaning surface component **4106**. Although not within view, motor **2118** is also operably connected to power source **4147**. Motor **2118** effects rotation of rotary mechanism **2116**.

Typically, cleaning material support components of cleaning devices and/or cleaning material components include one or more alignment features that are structured to align those components relative to one another when the cleaning material components are disposed in the cleaning material receiving areas of the cleaning devices. In one exemplary embodiment, for example, cleaning material support structure **4130** and cleaning material support component **4104** include alignment features **4142** and **4144**, respectively (schematically shown as corresponding tongue and groove-type components), that are structured to align cleaning material support structure **4130** relative to cleaning material support component **4104** cleaning device **4100**.

The cleaning devices of the invention typically include one or more handle components. As shown in FIGS. **41N-P**, for example, cleaning device **4100** includes handle **4146** operably connected to head component **4102**. Handle **4146** is pivotally connected to head component **4102** via pivot mechanism **4148** (shown as a ball and socket mechanism). As also shown, handle **4146** includes switch **4150** which is operably connected to motor **4143**. Switch **4150** is used to effect movement of cleaning material **4126** via the conveyance mechanism described above.

In some embodiments, cleaning devices include fluid handling mechanisms that can be used, for example, to distribute fluid (e.g., a cleaning fluid, etc.) to a surface to be cleaned, to a cleaning material of a cleaning device (e.g., to moisten the cleaning material prior to or during use of the cleaning device,

51

etc.), and/or the like. To illustrate one exemplary embodiment, cleaning device **4100** includes a fluid handling mechanism that comprises a fluid source (container **4154**) and fluid outlets (nozzles **4152**) (shown disposed proximal to a surface of head component **4102**). The fluid handling mechanism is configured to convey fluid from container **4154** to nozzles **4152**, which communicate via fluid conduit **4156**. The fluid handling mechanism of cleaning device **4100** also includes pumping mechanism **4158** (e.g., a rotary lobe pump, a rotary gear pump, a screw pump, a gear pump, a peristaltic pump, or the like) that is configured to pump the fluid from container **4154** to nozzles **4152**. As also shown, the fluid handling mechanism also includes vaporization component **4160** (e.g., a steam vaporizer or the like) that is configured to vaporize the fluid at least proximal to nozzles **4152**. In the embodiment shown, container **4154** is removable from cleaning device **4100** such that container **4154** can be, e.g., refilled with a cleaning fluid, replaced with a new container when container **4154** is fabricated as a consumable component of cleaning device **4100**, etc. In some embodiments, containers are fabricated integral or otherwise fixedly attached to cleaning devices. Switch **4150** is also configured to effect operation of pumping mechanism **4158** and vaporization component **4160**. As shown in FIG. **41Q**, for example, head component **4102** of cleaning device **4100** includes elevational element **4162** from a side view. Elevational elements are also described in, e.g., U.S. Provisional Patent Application No. 61/317,746, entitled "CLEANING IMPLEMENTS, CLEANING MATERIAL COMPONENTS, AND RELATED METHODS", filed on Mar. 26, 2010, which is incorporated by reference in its entirety.

In some embodiments, the cleaning devices or components thereof of the invention are optionally adapted for use as part of various types of robotic cleaning implements. Exemplary robotic cleaners or aspect thereof that are optionally adapted for use with these cleaning implements or components are described in, e.g., U.S. Pat. No. 7,571,511, entitled "Autonomous floor cleaning robot" to Jones et al, which issued Aug. 11, 2009; U.S. Pat. No. 7,620,476, entitled "Autonomous surface cleaning robot for dry cleaning" to Morse et al., which issued Nov. 17, 2009; U.S. Pat. No. 7,636,982, entitled "Autonomous floor cleaning robot" to Jones et al, which issued Dec. 29, 2009; and U.S. Pat. No. 7,761,954, entitled "Autonomous surface cleaning robot for wet and dry cleaning" to Ziegler et al., which issued Jul. 27, 2010; and U.S. Patent Application Publication Nos. US 2009/0281661, entitled "Application of localization, positioning & navigation systems for robotic enabled mobile products" by Dooley et al., which published Nov. 12, 2009 and US 2009/0306822, entitled "Multi-function robotic device" by Augenbraun et al., which published Dec. 10, 2009, which are each incorporated by reference herein in their entirety.

FIGS. **49 A-C** schematically depict a tooth brushing device or components thereof from various views according to one exemplary embodiment of the invention. As shown, tooth brushing device **4900** includes rotary mechanism **4300**, as described herein. Tooth brushing device **4900** also includes toothbrush head component **4902** and handle component **4904**. Toothbrush head component **4902** includes rotary mechanism housing **4906**, which partially exposes a portion of the implements of rotary mechanism **4300** through an opening in rotary mechanism housing **4906**. Rotary mechanism **4300** is operably connected to motor **4302** via shaft component **4908**. Motor **4302** is housed in handle component **4904**. A power source, such as a rechargeable battery or the like is also housed in handle component **4904** in some embodiments. As shown, for example, battery component

52

4910 is operably connected to motor **4302** in handle component **4904**. In certain embodiments, the motor is optionally connected to other types of power sources, such as photovoltaic cells attached to handle component **4904**, external power sources, or the like. As also shown, handle component **4904** also include switch **4912**, which is used, e.g., to turn tooth brushing device **4900** on and off, regulate speeds or modes of rotary unit rotation, or the like. Additional details regarding tooth brushing devices or components thereof are described herein.

FIGS. **50 A-E** schematically show a hair cutting device or components thereof from various views according to one exemplary embodiment of the invention. As shown, hair cutting device **5000** includes housing **5002**, which includes an opening that partially exposes rotary mechanism **5004**. Rotary mechanism **5004** is configured similar to rotary mechanism **4300** or components thereof, which is described further herein. For example, rotary mechanism **5004** includes rotational components **4204**, which include cutting implements **5006** (e.g., razor blades or other sharp edges) that are configured to cut hair via the opening in housing **5002**. Hair cutting device **5000** also includes removable structure **5008** (e.g., a shaving foil structure or the like) disposed in the opening in housing **5002**. Removable structure **5008** comprises holes via which hair is cut when the rotational components **4204** of rotary mechanism **5004** rotate and cutting implements **5006** contact the hair. As also shown, rotary mechanism **5004** is operably connected to motor **4302** via a shaft component. Motor **4302** is configured to effect rotation of rotational components **4204** of rotary mechanism **5004**. Switch **5010** (e.g., on/off switch, a variable speed control switch, and/or the like) is operably connected to motor **4302**. In addition, hair cutting device **5000** also includes battery component **5012** (e.g., rechargeable or not) operably connected to motor **4302**. Other power sources, such as power cords that plug into a wall sockets, photovoltaic cells, etc. are also optionally used in certain embodiments. Additional details regarding hair cutting devices or components thereof are described herein.

FIGS. **52 A and B** schematically show a tooth brushing device or components thereof from various views according to one exemplary embodiment of the invention. As shown, tooth brushing device **5200** includes rotary mechanism **5100**, as described herein. Tooth brushing device **5200** also includes toothbrush head component **5202** and handle component **5204**. Toothbrush head component **5202** includes rotary mechanism housing **5206**, which partially exposes a portion of the implements of rotary mechanism **5100** through an opening in rotary mechanism housing **5206** during operation. Rotary mechanism **5100** is operably connected to motor **5110** via shaft component **5102**. Motor **5110** is housed in handle component **5204**. A power source, such as a rechargeable battery or the like is also housed in handle component **5204** in some embodiments. As shown, for example, battery component **5208** is operably connected to motor **5110** in handle component **5204**. In certain embodiments, the motor is optionally connected to other types of power sources, such as photovoltaic cells attached, e.g., to handle component **5204**, external power sources, or the like. As also shown, handle component **5204** also include switch **5210**, which is used, e.g., to turn tooth brushing device **5200** on and off, regulate speeds or modes of rotary unit rotation, or the like. Additional details regarding tooth brushing devices or components thereof are described herein.

Device components (e.g., rotary units, rotary mechanisms, drive mechanism components, gear components, shafts, rotational components, device housings, doors, support struc-

tures, etc.) are optionally formed by various fabrication techniques or combinations of such techniques including, e.g., cast molding, stamping, machining, embossing, extrusion, engraving, injection molding, etching (e.g., electrochemical etching, etc.), or other techniques. These and other suitable fabrication techniques are generally known in the art and described in, e.g., Molinari et al. (Eds.), *Metal Cutting and High Speed Machining*, Kluwer Academic Publishers (2002), Altintas, *Manufacturing Automation: Metal Cutting Mechanics, Machine Tool Vibrations, and CNC Design*, Cambridge University Press (2000), Stephenson et al., *Metal Cutting Theory and Practice*, Marcel Dekker (1997), Fundamentals of Injection Molding, W. J. T. Associates (2000), Whelan, *Injection Molding of Thermoplastics Materials*, Vol. 2, Chapman & Hall (1991), Rosato, *Injection Molding Handbook*, 3.sup.rd Ed., Kluwer Academic Publishers (2000), Fisher, *Extrusion of Plastics*, Halsted Press (1976), and Chung, *Extrusion of Polymers: Theory and Practice*, Hanser-Gardner Publications (2000), which are each incorporated by reference. Exemplary materials optionally used to fabricate device components include, e.g., metal, glass, wood, polymethylmethacrylate, polyethylene, polydimethylsiloxane, polyetheretherketone, polytetrafluoroethylene, polystyrene, polyvinylchloride, polypropylene, polysulfone, polymethylpentene, and polycarbonate, among many others. In certain embodiments, following fabrication, device components are optionally further processed, e.g., by painting, coating surfaces with a hydrophilic coating, a hydrophobic coating, or the like.

Exemplary rotary units, rotational mechanisms, related applications, and other aspects, which are optionally adapted, e.g., for use with the rotary units and rotational mechanisms described herein are also described in, e.g., U.S. patent application Ser. No. 12/577,326, entitled "ROTARY UNITS, MECHANISMS, AND RELATED DEVICES", filed on Oct. 12, 2009, U.S. Provisional Patent Application No. 61/104,748, entitled "ROTARY UNITS, MECHANISMS, AND RELATED DEVICES", filed on Oct. 12, 2008, International Application No. PCT/US2009/060386, entitled "ROTARY UNITS, MECHANISMS, AND RELATED DEVICES", filed on Oct. 12, 2009, U.S. Provisional Patent Application No. 61/365,290, entitled "ROTARY UNITS, MECHANISMS, AND RELATED DEVICES", filed on Jul. 16, 2010, and U.S. Provisional Patent Application No. 61/317,746, entitled "CLEANING IMPLEMENTS, CLEANING MATERIAL COMPONENTS, AND RELATED METHODS", filed on Mar. 26, 2010, which are each incorporated herein by reference in their entirety for all purposes.

While the foregoing invention has been described in some detail for purposes of clarity and understanding, it will be clear to one skilled in the art from a reading of this disclosure that various changes in form and detail can be made without departing from the true scope of the invention. For example, all the techniques and apparatus described above can be used in various combinations. All publications, patents, patent applications, and/or other documents cited in this application are incorporated by reference in their entirety for all purposes to the same extent as if each individual publication, patent, patent application, and/or other document were individually indicated to be incorporated by reference for all purposes.

What is claimed is:

1. A cleaning device, comprising:

at least one head component that comprises at least one cleaning material support component and at least one cleaning surface component, wherein the cleaning material support component comprises at least one cleaning material support component surface that at least par-

tially defines at least one cleaning material receiving area, wherein the cleaning material support component comprises at least one opening such that the cleaning material receiving area communicates with the cleaning surface component, and wherein the cleaning material receiving area is configured to receive at least one cleaning material such that at least a portion of the cleaning material is movable to and/or from the cleaning material receiving area to extend over at least a portion of the cleaning surface component when the cleaning material is at least partially disposed in the cleaning material receiving area; and,

at least one rotary mechanism comprising:

at least first, second, and third rotational components that substantially, coaxially rotate relative to one another and that each comprise at least one implement;

at least first and second counter-rotational mechanisms, wherein the first counter-rotational mechanism operably engages at least the first and second rotational components, and wherein the second counter-rotational mechanism operably engages at least the second and third rotational components; and,

at least one drive mechanism component or a portion thereof operably engaged with one or more of the rotational components and/or with one or more of the counter-rotational mechanisms, which drive mechanism component or portion thereof is configured at least to effect rotation of the rotational components and the counter-rotational mechanisms such that the first and third rotational components rotate in a first direction when the second rotational component rotates in a second direction.

2. The cleaning device of claim 1, wherein at least one of the implements comprises a plurality of bristles.

3. The cleaning device of claim 1, comprising at least two cleaning material support components that are each configured to receive at least a component of the cleaning material.

4. The cleaning device of claim 1, wherein the cleaning surface component comprises at least one elevational element.

5. The cleaning device of claim 1, comprising at least one handle operably connected to the head component.

6. The cleaning device of claim 1, comprising the cleaning material at least partially disposed in the cleaning material receiving area of the cleaning material support component.

7. The cleaning device of claim 6, wherein at least one cleaning material cartridge comprises the cleaning material.

8. The cleaning device of claim 1, comprising at least one conveyance mechanism, or at least one component thereof, that is configured to convey at least the cleaning material over at least the portion of the cleaning surface component when the cleaning material is at least partially disposed in the cleaning material receiving area.

9. The cleaning device of claim 8, wherein the conveyance mechanism is manually operated via at least one manual conveyance component.

10. The cleaning device of claim 8, wherein the conveyance mechanism or the component thereof is configured to operably engage the cleaning material to effect conveyance of the cleaning material when the cleaning material is at least partially disposed in the cleaning material receiving area.

11. The cleaning device of claim 8, wherein the conveyance mechanism comprises at least one motor component that is configured to effect conveyance of the cleaning material when the cleaning material is at least partially disposed in the cleaning material receiving area.

12. The cleaning device of claim 1, comprising at least one fluid handling mechanism or at least one component thereof that is configured to convey at least one fluid from at least one fluid source to at least one fluid outlet.

13. The cleaning device of claim 12, wherein the fluid outlet communicates with the cleaning material or a portion thereof when the cleaning material is at least partially disposed in the cleaning material receiving area.

14. The cleaning device of claim 12, wherein the fluid outlet is disposed proximal to at least one surface of the head component.

15. The cleaning device of claim 12, wherein the fluid handling mechanism comprises at least one pumping mechanism that is configured to pump the fluid from the fluid source to the fluid outlet.

16. The cleaning device of claim 12, wherein the fluid handling mechanism comprises at least one vaporization component that is configured to vaporize the fluid at least proximal to the fluid outlet.

17. The cleaning device of claim 12, wherein the fluid source and fluid outlet communicate via at least one fluid conduit.

18. The cleaning device of claim 12, wherein the fluid source comprises at least one fluid container.

19. The cleaning device of claim 18, wherein the fluid container is removable.
